d. Routine practices only, because antibiotics have already started and the patient is no longer contagious

Answer: b — Ontario public health guidance calls for droplet precautions for a hospitalized patient with invasive meningococcal disease until 24 hours of antibiotics have been given (b; section 30.6). The organism spreads by respiratory droplets and throat secretions, not by the airborne route (a) and not mainly by surfaces (c). Six hours of antibiotics is not enough to stop precautions (d).

36. [CORE] A patient with fever and confusion has dark skin. The nurse suspects meningococcal disease. Where should the nurse look most closely for a petechial rash?

a. On the back and the buttocks, where pressure makes petechiae easiest to see on any skin tone

b. On the forehead and the cheeks, where the rash of meningitis always begins first

c. On the palms, the soles and the inside of the eyelids, where the skin is paler

d. On the chest only, because a petechial rash does not appear on the hands or the feet

Answer: c — PHAC notes that the rash is harder to see on darker skin and advises checking paler areas such as the palms, soles and inside of the eyelids, as well as the palate (c; section 30.6). Pressure areas are not where the rash is most visible (a). The rash does not always start on the face (b). Petechiae can appear on the hands and feet (d).

37. [CORE] An RPN on a neurosurgery unit notices that a patient's right pupil is now larger and slower than the left. One hour ago the pupils were equal and brisk. What should the RPN do?

a. Document the finding and recheck the pupils at the next scheduled neurologic check in 1 hour.

b. Ask the patient whether the light is bothering the eyes, and dim the room before rechecking.

c. Notify the RN and the physician immediately, stay with the patient and repeat the neurologic check.

d. Wait to report the finding until the GCS score has also dropped, so the report will be complete.

Answer: c — A new unequal or sluggish pupil is an urgent cue; every nurse acts at once and escalates, and the RPN informs the RN and the physician immediately (c; section 30.6, Scope in Practice box). Waiting an hour could allow herniation to progress (a). Dimming the room delays escalation (b). The nurse does not wait for other signs before reporting (d).

38. [CORE] An RPN is asked to take over the care of a patient with an external ventricular drain. The RPN has never been taught EVD care, and the unit's policy limits EVD care to RNs with neurosurgical education. What should the RPN do?

a. Accept the assignment and learn EVD care by watching the RN level the drain at the start of the shift.

b. Accept the assignment but clamp the drain for the whole shift so that it does not need adjusting.

c. Accept the assignment and ask the patient's family to report any change in the drain's fluid.

d. Explain the limit to the charge nurse so that an educated RN manages the EVD, and ask how to help.

Answer: d — The RPN lacks the competence, and the employer's policy (context) does not support the activity, so the RPN declines EVD care and works with the charge nurse to arrange an educated RN (d; section 30.6, Scope in Practice box). Watching once does not provide competence (a). Clamping a drain without an order can let ICP rise dangerously (b). Families cannot take on nursing monitoring (c).

39. [RN] A patient with a severe brain injury has a mean arterial pressure of 78 mm Hg and an intracranial pressure of 24 mm Hg. Which interpretation is correct?

a. The CPP is 102 mm Hg, which is above the target range and calls for lowering the blood pressure.

b. The CPP is 54 mm Hg, which is below the 60 to 70 mm Hg target and should be reported at once.

c. The CPP is 54 mm Hg, which is within the expected range for a patient with a brain injury.

d. The CPP cannot be calculated without the systolic blood pressure and the heart rate.

Answer: b — CPP equals MAP minus ICP: 78 − 24 = 54 mm Hg, which is below the Neurocritical Care Society target of 60 to 70 mm Hg, and the ICP is also above 22 mm Hg; both need prompt reporting (b; section 30.4, Going Deeper box). Adding the values gives the wrong answer (a). A CPP of 54 mm Hg is below target (c). The calculation uses MAP and ICP only (d).

40. [RN] A patient is receiving hypertonic saline per protocol to lower intracranial pressure. Which monitoring is the priority?

a. Serum sodium checked at the intervals the protocol sets, with results outside the set limit reported

b. Serum potassium checked once daily, because hypertonic saline mainly lowers the potassium level

c. Blood glucose checked every hour, because hypertonic saline causes severe hyperglycemia

d. Hemoglobin checked every 4 hours, because hypertonic saline commonly causes bleeding

Answer: a — The Neurocritical Care Society protocol calls for serum sodium checks every 4 to 6 hours during hypertonic saline and sets an upper sodium limit, so the nurse follows the ordered schedule and reports results outside the limit (a; section 30.4, Table 30.4). Potassium is not the main concern with hypertonic saline (b). Hypertonic saline does not cause severe hyperglycemia (c). Bleeding is not a common effect that needs this monitoring (d).

31 Stroke

LEARNING OUTCOMES & COMPETENCY MAPPING

By the end of this chapter, you will be able to:

1. Explain the types of stroke and TIA, the penumbra and why time matters, and describe who is at risk in Canada.
2. Recognize stroke using FAST, rule out common mimics and act on a suspected stroke, including in hospital.
3. Provide nursing care for adults receiving thrombolysis or endovascular thrombectomy as the Canadian Stroke Best Practice Recommendations describe.
4. Care for adults with intracerebral and subarachnoid hemorrhage, recognizing neurologic deterioration.
5. Provide stroke unit care, including dysphagia screening, positioning, communication with aphasia and prevention of complications, using the CJMM.
6. Support secondary prevention, rehabilitation, transitions and caregivers after stroke.
7. Distinguish RN and RPN roles in stroke care using CNO's authority, competence and context.

How the outcomes map to the CNO entry-to-practice competencies

Outcome	RN competency role (CNO, 2019a)	RPN competency category (CNO, 2019b)
1, 2, 3, 4, 5	Clinician; Scholar	Foundations of Practice
5, 6	Educator; Collaborator; Advocate	Collaborative Practice; Foundations of Practice
7	Professional; Coordinator	Legal Practice; Collaborative Practice

Introduction

A stroke can change a life in minutes. A person who was talking at breakfast may, by lunch, be unable to lift an arm, find a word or swallow safely. Stroke is common in Canada, and it is one of the leading causes of death and of lasting disability. Yet much of the harm is not fixed at the moment symptoms start. Brain tissue at risk can still be saved when blood flow returns quickly, and many complications in the days after a stroke can be prevented. Nurses shape both outcomes. They are often the first to notice new signs, in the community and on hospital units, and they deliver much of the care that follows.

This chapter is the book's home for stroke. Section 31.1 explains the types of stroke, why time matters and who has a stroke in Canada. Section 31.2 teaches how to recognize stroke with the FAST signs, how to rule out conditions that look like stroke and how a code stroke unfolds, including a stroke that begins in hospital. Section 31.3 covers hyperacute treatment: clot-dissolving medicine, clot removal and organized stroke unit care. The second half of the chapter covers intracerebral and subarachnoid hemorrhage (31.4), stroke unit nursing care and secondary prevention (31.5), and rehabilitation, transitions and life after stroke (31.6).

Throughout, the chapter follows the Canadian Stroke Best Practice Recommendations (CSBPR) from Heart & Stroke and states each recommendation as the current module gives it. It builds on earlier chapters. Scope of practice for registered nurses (RNs) and registered practical nurses (RPNs) is taught in section 1.3, and the Clinical Judgment Measurement Model (CJMM) in section 1.4. Recognizing deterioration and the SBAR (situation, background, assessment, recommendation) format are in Chapter 6. The neurologic assessment and the Glasgow Coma Scale (GCS) are in section 30.2. In other provinces and territories, practical nurses (PNs) are often called licensed practical nurses (LPNs); this chapter uses "the nurse" unless the roles differ.

31.1 Understanding Stroke

Types of Stroke

A **stroke** is a sudden loss of brain, spinal cord or retinal function caused by a blocked or bleeding blood vessel, with evidence of brain injury on imaging (Heart and Stroke Foundation of Canada, 2022). The cause decides the treatment, so the first question in every suspected stroke is whether the vessel is blocked or bleeding (Figure 31.1).

An **ischemic stroke** happens when a blocked artery starves part of the brain, spinal cord or retina of blood until cells die (Heart and Stroke Foundation of Canada, 2022). Most strokes are ischemic (Heart and Stroke Foundation of Canada, n.d.-d). A widely used research classification, the Trial of Org 10172 in Acute Stroke Treatment (TOAST) classification, sorts ischemic strokes by cause into large-artery atherosclerosis, cardioembolism, small-vessel occlusion, other known causes and unknown causes (Adams et al., 1993). In plain terms, there are three common mechanisms:

- **Thrombotic:** a clot forms on a fatty plaque inside a large artery in the neck or brain and narrows or closes it.
- **Embolic:** a clot forms elsewhere, often in the heart, then travels and lodges in a brain artery. Atrial fibrillation is a common source (Chapter 16).
- **Small vessel (lacunar):** one of the tiny deep arteries closes, causing a small but sometimes disabling stroke.

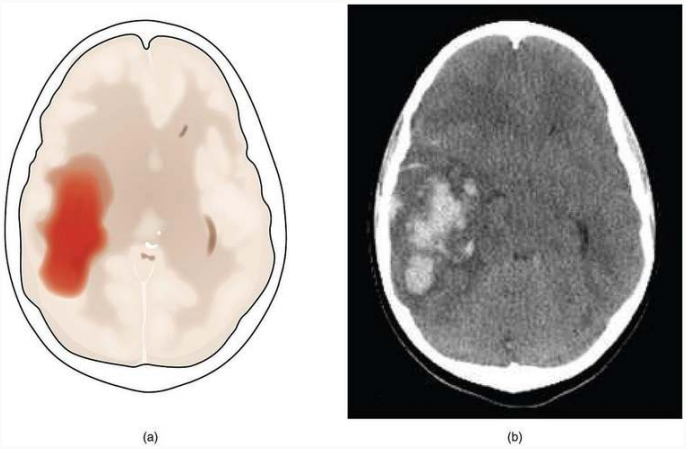

Figure 31.1 Intraparenchymal hemorrhagic stroke: (a) schematic axial view and (b) corresponding non-contrast head CT showing a large hemorrhage compressing the ipsilateral ventricle and shifting the midline. (credit: “1602 The Hemorrhagic Stroke-02” by OpenStax College/Wikimedia Commons, CC BY 3.0)

A **hemorrhagic stroke** is caused by a vessel that ruptures and bleeds into or around the brain (Heart and Stroke Foundation of Canada, 2022). An **intracerebral hemorrhage (ICH)** is bleeding into the brain tissue itself that is not caused by trauma. A **subarachnoid hemorrhage (SAH)** is bleeding into the space between the brain and its thin covering membranes, often from a ruptured aneurysm. Both are covered in section 31.4.

A **transient ischemic attack (TIA)** is a brief episode of stroke-like symptoms caused by ischemia, with no infarct on imaging. Symptoms resolve completely within 24 hours, and usually within an hour (Heart and Stroke Foundation of Canada, 2022). A TIA is a warning. People seen within 48 hours of a new TIA or stroke are at the highest risk of another stroke, so the CSBPR call for urgent assessment (Heart and Stroke Foundation of Canada, 2022). Section 31.5 describes TIA triage. Table 31.1 compares the main types of stroke.

Why Time Matters

When an artery closes, brain tissue does not all die at once. Blood flow falls most at the centre of the affected area, the **ischemic core**, where damage quickly becomes permanent. Around it lies the **penumbra**, tissue whose cells have stopped working but can still recover if blood flow returns (Mangiardi et al., 2023). Small side branches called collateral vessels keep the penumbra alive for a time. Their strength varies from person to person, which is why some people can still benefit from treatment many hours after onset. Collaterals cannot protect the penumbra forever, however. Without restored blood flow, it becomes part of the core (Mangiardi et al., 2023).

The phrase "time is brain" captures this race. One widely cited estimate is that a typical person with an untreated large-vessel ischemic stroke loses about 1.9 million neurons every minute. By the same estimate, each untreated hour ages the affected brain by about 3.6 years (Saver, 2006). Treatments that restore blood flow are the only ones that change the course of an ischemic stroke, and their effect on recovery depends directly on how early they are given (Mangiardi et al., 2023). For the nurse, the lesson is practical:

every step in finding, reporting and treating a stroke should happen without delay. A few minutes lost while waiting to see whether a weak arm improves, or while looking for a missing chart, are minutes of brain lost.

Who Has a Stroke in Canada

Heart & Stroke reports that Canada has more than 108,000 strokes a year, about one every five minutes, and that close to one million people in Canada live with the effects of stroke (Heart and Stroke Foundation of Canada, 2025e). Stroke ranks fourth among causes of death in Canada. About 60% of survivors have some stroke-related disability, and more than 40% have moderate to severe disability (Heart and Stroke Foundation of Canada, 2025e).

Stroke can happen at any age, but about 80% of strokes occur in people over 60, and about 1 in 20 occur in people under 45 (Heart and Stroke Foundation of Canada, 2025e). Age and sex cannot be changed. Family history also adds risk, although many Canadians wrongly believe it is the biggest risk factor (Heart and Stroke Foundation of Canada, 2025e).

Most risk can be changed. High blood pressure is the single most important risk factor that people can change (Public Health Agency of Canada [PHAC], 2017; Heart and Stroke Foundation of Canada, 2025e). People with atrial fibrillation have double the risk of stroke (Heart and Stroke Foundation of Canada, 2025e). Heart & Stroke also lists diabetes, high cholesterol, smoking, physical inactivity, unhealthy diet, unhealthy weight, stress and excessive alcohol use as risk factors (Heart and Stroke Foundation of Canada, n.d.-b). Nine in 10 people in Canada have one or more risk factors for heart disease or stroke, and Heart & Stroke estimates that as many as 80% of premature cases of stroke or heart disease could be prevented through healthy behaviours (Heart and Stroke Foundation of Canada, 2025e). Every hospital stay is therefore a chance to find and treat risk factors, such as an undiagnosed high blood pressure or an irregular pulse, and to teach the person about them. Hypertension is taught in Chapter 19, diabetes in Chapter 22 and secondary prevention after stroke in section 31.5.

Women face particular risks. Men have higher stroke rates, but women have more strokes than men each year, partly because women live longer (PHAC, 2017). About 30 in 100,000 women have a stroke during pregnancy (Heart and Stroke Foundation of Canada, 2025e). The 2022 update of the CSBPR acute module added sex and gender considerations (Heart and Stroke Foundation of Canada, 2022).

Stroke risk and care are also shaped by structural factors. In an Ontario study of adults with diabetes, First Nations people had higher rates of hospital admission for stroke or TIA than other Ontarians with diabetes in most years studied. They were less likely to receive clot-dissolving treatment (6.3% vs. 11.0%) (Kapral et al., 2020). The authors place these gaps in the context of the ongoing effects of colonization and marginalization, note that First Nations people are more likely to live outside urban settings, and call for research on Indigenous-specific determinants of health (Kapral et al., 2020). Distance is a barrier for many rural, remote and northern communities (see the Canadian Context box in section 31.3). Culturally safe care is taught in Chapter 2.

Table 31.1 Types of stroke compared (Adams et al., 1993; Heart and Stroke Foundation of Canada, 2022, 2025a)

Type	Cause	Typical onset and signs	Key early treatment	Nursing focus
Ischemic, thrombotic (large artery)	Clot forms on plaque in a large neck or brain artery	Sudden, sometimes stuttering or worse on waking; weakness, speech or vision loss	Clot-dissolving medicine if eligible; clot removal for a large-vessel blockage	Last known well, glucose, rapid imaging, nothing by mouth until swallow screen
Ischemic, embolic	Clot travels from the heart (often atrial fibrillation) or a large artery	Sudden and often maximal at onset	As for thrombotic; prevent another embolus (Chapter 16)	Same as thrombotic; heart rhythm monitoring
Ischemic, small vessel (lacunar)	Closure of a small deep artery	Sudden pure weakness or numbness of one side, often without language loss	Clot-dissolving medicine if eligible and disabling	Do not dismiss mild deficits; frequent neurologic checks
Intracerebral hemorrhage	Bleeding into brain tissue, not from trauma	Sudden deficit, often with headache, vomiting or falling level of consciousness	Blood pressure lowering and anticoagulant reversal as ordered (31.4)	Neurologic checks, airway, signs of rising pressure (section 30.4)

Type	Cause	Typical onset and signs	Key early treatment	Nursing focus
Subarachnoid hemorrhage	Bleeding around the brain, often from a ruptured aneurysm	Sudden, very severe headache; may lose consciousness	Securing the aneurysm in a specialized centre (31.4)	Neurologic checks, pain, early signs of rebleeding or new deficit
Transient ischemic attack	Brief ischemia without infarct	Stroke signs that fully resolve, usually within an hour	Urgent assessment and imaging; start prevention (31.5)	Treat as an emergency; teach FAST and calling 9-1-1

31.2 Recognizing Stroke and Code Stroke

Signs of Stroke

Heart & Stroke teaches the public to recognize stroke with **FAST**, a memory aid for the most common signs (Heart and Stroke Foundation of Canada, 2023): (Figure 31.2)

- **F**ace: is it drooping?
- **A**rms: can you raise both?
- **S**peech: is it slurred or jumbled?
- **T**ime: to call 9-1-1.

The FAST signs are the signs most likely to be caused by stroke rather than another condition (Heart and Stroke Foundation of Canada, n.d.-a). Heart & Stroke also lists less common sudden signs: blurred, double or otherwise changed vision; a sudden, severe headache, which usually comes with other signs; numbness, most often of one side of the body; and trouble with balance (Heart and Stroke Foundation of Canada, n.d.-a). Not everyone has every sign; one is enough to call 9-1-1. Knowing the exact time the signs began matters for treatment (Heart and Stroke Foundation of Canada, n.d.-a). Heart & Stroke advises against driving to hospital, because an ambulance will take the person to the nearest hospital able to give urgent stroke care (Heart and Stroke Foundation of Canada, n.d.-c). Stroke awareness campaigns work: mass media education can raise symptom recognition and the likelihood of calling emergency services (Heran et al., 2024).

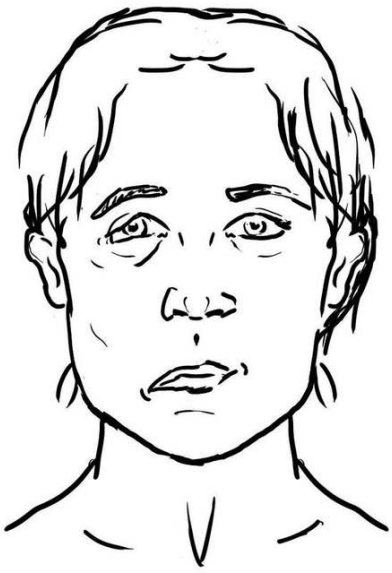

Figure 31.2 Unilateral facial droop—asymmetry of the lower face and mouth—one of the core signs in the FAST™ stroke recognition tool. (credit: "Stroke-facial-droop" by Another-anon-artist-234/Wikimedia Commons, CC0)

The key word is **sudden**. Stroke signs appear over seconds to minutes. Each hemisphere controls the opposite side of the body (section 30.1), so a stroke in one hemisphere causes **hemiparesis**, weakness of the face, arm or leg on the opposite side. A left hemisphere stroke can also cause **aphasia**, a disorder of language that affects speaking, understanding, reading or writing, because language depends mainly on the left hemisphere in most people (section 30.2). A right hemisphere stroke can cause **neglect**, in which the person does not attend to one side of space or their own body. The person may eat from only one side of the plate or not notice a weak arm. In a systematic review, neglect occurred in about 38% of people after right brain damage and 18% after left brain damage (Esposito et al., 2021). Slurred speech from weak muscles, called dysarthria, is different from aphasia (section 30.2).

Stroke signs are judged by movement, symmetry, speech and vision, not by skin colour, so the nurse finds them the same way on every skin tone. The nurse compares the two sides of the face during a smile, watches for one arm drifting down and listens to the person's speech.

Stroke Mimics

A **stroke mimic** is a condition that causes sudden stroke-like signs but is not a stroke. Mimics are common. Depending on who does the assessment, they make up about 20% to 50% of suspected strokes (Buck et al., 2021). Common mimics include:

- **Low blood glucose:** hypoglycemia can cause one-sided weakness, confusion or slurred speech that resolves once glucose is corrected (section 22.4). High glucose can also mimic stroke (Buck et al., 2021).
- **Seizure:** after a seizure, a person can have temporary weakness of one side, called postictal (Todd's) paralysis (Buck et al., 2021). Seizures are covered in section 30.5.
- **Migraine with aura:** aura, sometimes without headache, can cause temporary neurologic signs (Buck et al., 2021).
- **Infection and sepsis:** infection can cause confusion and other stroke-like signs (Buck et al., 2021; Chapter 4).
- **Functional neurologic disorders, tumours and other causes** (Buck et al., 2021).

A gradual onset, fluctuating signs, a history of migraine or seizures, or signs that do not match one blood vessel's territory raise the suspicion of a mimic (Buck et al., 2021). These are clues for the team, not reasons for the nurse to delay. The safe approach is to treat every sudden deficit as a stroke until proved otherwise, check the glucose early, and let brain imaging and the stroke team decide.

CLINICAL SAFETY

Check the Glucose

A low blood glucose can look exactly like a stroke, and it is quick to find and fix. The CSBPR recommend a capillary blood glucose check by paramedics on scene and a glucose check on arrival in the emergency department. Hypoglycemia is corrected at once using local protocols (Heart and Stroke Foundation of Canada, 2022).

- Check the point-of-care glucose as soon as new stroke signs are found, including on a hospital unit.
- If the glucose is low, treat it at once as the hypoglycemia protocol directs (section 22.4), and still call for help: the person may have both a low glucose and a stroke.
- Report the value and time in the handover.
- Never give food or drink to treat a low glucose if swallowing is uncertain. Use the protocol's non-oral route.

The First Hour

Last known well (LKW) is the last time the person was known to be at their usual self, without the new signs. When no one saw the signs begin, such as when a person wakes with symptoms or a nurse finds them on rounds, treatment decisions use the LKW time, not the time the signs were found. Paramedics are asked to record both the onset time and the LKW time, the person's medications (especially anticoagulants) and any advance directives (Heart and Stroke Foundation of Canada, 2022). A family member or substitute decision-maker should come to hospital or stay reachable by phone, because the team may need facts and decisions quickly.

Before hospital. Anyone who sees stroke signs should call 9-1-1 immediately. Paramedics use a validated screening tool that includes the FAST components, then a second screen for stroke severity that helps identify a likely **large vessel occlusion (LVO)**, a blockage of a major brain artery (Heart and Stroke Foundation of Canada, 2022). On-scene time should be as short as possible, ideally a median under 20 minutes. Transport protocols direct possible candidates for clot-dissolving treatment or clot removal to the most appropriate stroke centre, which may mean bypassing a closer hospital. Paramedics notify the receiving emergency department on the way so it can activate a code stroke (Heart and Stroke Foundation of Canada, 2022). Pre-notification raised the odds of receiving clot-dissolving treatment in studies reviewed for the CSBPR (Heran et al., 2024).

In the emergency department. A **code stroke** is a hospital's emergency process that brings the stroke team, imaging and laboratory together at once for a person with suspected acute stroke. Most patients with suspected stroke are triaged at Canadian Triage and Acuity Scale (CTAS) level 2, or level 1 if airway, breathing or circulation is compromised (Heart and Stroke Foundation of Canada, 2022). The team checks airway, breathing and circulation, does a rapid neurologic examination that includes a standardized stroke

scale, for example the National Institutes of Health Stroke Scale (NIHSS), and records vital signs, heart rhythm, oxygen saturation, temperature and point-of-care glucose. The team also asks about anticoagulant use and the time of the last dose (Heart and Stroke Foundation of Canada, 2022). Blood tests include electrolytes, glucose, a complete blood count, clotting tests and creatinine, but they must not delay imaging or treatment decisions. A 12-lead electrocardiogram (ECG) looks for atrial fibrillation but also must not delay assessment for treatment (Heart and Stroke Foundation of Canada, 2022). A seizure at onset does not by itself rule out clot-dissolving treatment or clot removal. Supplemental oxygen is not needed when the oxygen saturation is normal (Heart and Stroke Foundation of Canada, 2022). The nurse's role in the emergency department is to keep the process moving: weighing the patient, starting intravenous (IV) access, sending blood work, getting the patient to computed tomography (CT) and recording times.

Brain and vessel imaging is the most urgent test. For a person who arrives within 6 hours and may be eligible for treatment, the CSBPR recommend immediate non-contrast CT of the head with **CT angiography (CTA)**, which uses contrast dye to show the arteries from the aortic arch to the top of the head (Heart and Stroke Foundation of Canada, 2022). The non-contrast CT shows whether there is bleeding; the CTA shows where an artery is blocked. A performance measure is brain imaging within 15 minutes of arrival for eligible patients (Heart and Stroke Foundation of Canada, 2022). Between 6 and 24 hours, perfusion imaging may help select patients for clot removal.

In-hospital stroke. Some strokes begin in people who are already in hospital for another reason. An Ontario Stroke Registry study found that these patients were diagnosed and treated significantly later than patients who came from the community (Saltman et al., 2015). The study's authors called for standardized approaches. Many hospitals now have an in-hospital code stroke or use the rapid response team (Chapter 6). The nurse who finds new stroke signs stays with the patient and calls for help as policy directs. The nurse then finds the LKW time, checks glucose and vital signs, gives nothing by mouth, and gives a clear SBAR report.

Nothing by mouth. Stroke can weaken the muscles of swallowing. The CSBPR state that patients stay **NPO** (nothing by mouth), including oral medications, until a swallowing screen with a validated tool has been completed by a trained professional (Heart and Stroke Foundation of Canada, 2022). Medications needed before then are given by another route as ordered. Section 31.5 describes the screen.

GOING DEEPER

The NIH Stroke Scale

Required for RN students; optional for PN students.

The NIHSS is a structured checklist that measures how severe a stroke is (National Institute of Neurological Disorders and Stroke [NINDS], n.d.). It rates 11 categories, including level of consciousness, gaze, visual fields, facial movement, arm and leg strength, coordination, sensation, language, speech and neglect. Each category has defined responses, and the examiner must choose a score even when a breathing tube or language barrier limits the examination (NINDS, n.d.). The maximum possible total is 42 points, and higher scores mean more severe deficits (Lyden, 2017).

Why the score matters:

- The CSBPR recommend a standardized scale such as the NIHSS in the initial emergency assessment (Heart and Stroke Foundation of Canada, 2022).
- The total relates to the size of the stroke, helps predict outcome and is used in treatment decisions. For example, the CSBPR describe disabling stroke for clot removal with an example threshold of an NIHSS score above 5 (Heart and Stroke Foundation of Canada, 2025a).
- Repeated scores show improvement or worsening over time.

The scale has limits. It captures brainstem function poorly, and left hemisphere strokes score about 4 points higher than right hemisphere strokes of the same size (Lyden, 2017). Because its rules are not intuitive, reliable scoring requires training and certification (Lyden, 2017); employers set their own certification requirements for nurses who use it.

31.3 Hyperacute Treatment

Thrombolysis

Thrombolysis is treatment with an intravenous medicine that dissolves the clot blocking a brain artery. Two thrombolytics are used in Canada: **alteplase** and **tenecteplase**. Tenecteplase was authorized by Health Canada for acute ischemic stroke in adults in November 2025, with treatment to start within 4.5 hours of symptom onset after bleeding in the brain has been ruled out (Hoffmann-La Roche Limited, 2025a, 2025b). Alteplase is given as a bolus followed by a 60-minute infusion; tenecteplase is a single bolus given over about 5 seconds (Hoffmann-La Roche Limited, 2025a). Doses are calculated by weight and prepared by protocol.

Eligibility in principle. The CSBPR recommend that eligible patients with a disabling ischemic stroke who can be treated within 4.5 hours of symptom onset or LKW be offered thrombolysis with alteplase or tenecteplase (Heart and Stroke Foundation of Canada, 2022). The Canadian alteplase product monograph states that treatment should start within 3 hours of symptom onset (Hoffmann-La Roche Limited, 2024), a narrower window than the CSBPR recommendation; the stroke physician makes the treatment decision. Eligibility depends on the LKW time, imaging that rules out hemorrhage, the severity of the deficit and the person's bleeding risk, including recent anticoagulant use. A stroke expert, on site or by telestroke, makes the decision with the person and family. Treatment beyond 4.5 hours may be considered with stroke expertise and advanced imaging (Heart and Stroke Foundation of Canada, 2022). People taking a direct oral anticoagulant are not routinely given thrombolysis; it may be considered only in comprehensive stroke centres with specialized testing and expert advice (Heart and Stroke Foundation of Canada, 2022). The nurse supports a fast, informed decision by telling the team about any anticoagulant and the time of the last dose, and by helping the family reach the bedside or the phone. Consent for emergency treatment is taught in section 1.5.

Door-to-needle time is the time from hospital arrival to the start of thrombolysis. The CSBPR target is a median of 30 minutes or less, and 60 minutes or less for at least 90% of treated patients (Heart and Stroke Foundation of Canada, 2022). Nurses help meet it by having weight, IV access, glucose and vital signs ready, and by moving the patient straight from CT to treatment when the protocol allows.

Blood pressure. For a person who will receive thrombolysis, the CSBPR state that blood pressure should be lowered and kept below 185/110 mm Hg when treatment starts, during treatment and for the next 24 hours (Heart and Stroke Foundation of Canada, 2022). For people who are not receiving reperfusion treatment, moderately high blood pressure is usually not treated in the first hours, and rapid or excessive lowering is avoided, because the penumbra depends on blood pressure to receive blood flow. Lowering may be considered when the pressure is extremely high, for example a systolic pressure above 220 mm Hg or a diastolic pressure above 120 mm Hg (Heart and Stroke Foundation of Canada, 2022). The prescriber orders the antihypertensive and the targets. Hypertension and its medicines are taught in Chapter 19.

Monitoring. The CSBPR call for close monitoring for the first 24 hours after thrombolysis (Heart and Stroke Foundation of Canada, 2022). The exact schedule of neurologic checks and blood pressure readings comes from the employer's post-thrombolysis protocol and orders (Table 31.2). The alteplase monograph advises minimizing arterial and venous punctures, avoiding intramuscular injections and avoiding nonessential handling during and right after treatment (Hoffmann-La Roche Limited, 2024).

Bleeding. The most feared complication is **symptomatic intracranial hemorrhage**, bleeding in the brain that worsens the person's condition. The CSBPR name a decline in neurologic status, a sudden rise in blood pressure or a new headache as reasons to suspect it (Heart and Stroke Foundation of Canada, 2022). Nausea, vomiting and a falling level of consciousness are also signs of rising intracranial pressure (section 30.4). If any of these appear, the nurse stops the infusion if it is still running, as the protocol directs, and calls the stroke physician at once. An urgent non-contrast CT and blood work follow (Heart and Stroke Foundation of Canada, 2022). Bleeding elsewhere also matters: gums, IV sites, urine, stool and vomit are checked. Bruising can be harder to see on darker skin, so the nurse also checks the mouth and asks about new pain or swelling.

Orolingual angioedema is swelling of the lips, tongue or throat that can follow thrombolysis and threaten the airway. It occurred in 1.1% of people who received tenecteplase in a Canadian trial, a rate similar to that with alteplase (Hoffmann-La Roche Limited, 2025b). The alteplase monograph notes that many affected people were taking an angiotensin-converting enzyme (ACE) inhibitor (Hoffmann-La Roche Limited, 2024). At the first sign, the CSBPR advise stopping the infusion if it is still running and treating with antihistamines, with other medicines and airway management as needed (Heart and Stroke Foundation of Canada, 2022). The nurse

stays with the patient, calls for help and prepares for airway support. Angioedema is taught in section 21.2 and anaphylaxis in section 6.5.

Endovascular Thrombectomy

Endovascular thrombectomy (EVT) removes a clot from a large brain artery with a catheter threaded from an artery in the groin or wrist (Elfil et al., 2023). It is done by a neurointerventionist in a comprehensive stroke centre and can follow thrombolysis or be used when thrombolysis is not possible. Neither treatment should delay the other (Heart and Stroke Foundation of Canada, 2025a).

The 2025 CSBPR interim update on EVT describes eligibility in principle. Candidates are adults who were independent before the stroke, have a disabling stroke and a blockage of a large artery in the front of the brain or the basilar artery that the catheter can reach, and have a core of damage on imaging that is not too large (Heart and Stroke Foundation of Canada, 2025a). Patients within 6 hours of onset should be screened without delay. Selected patients may be treated up to 24 hours from LKW, often with advanced imaging (Heart and Stroke Foundation of Canada, 2022, 2025a). The decision is shared among the stroke physician, the neurointerventionist and the patient and family (Heart and Stroke Foundation of Canada, 2025a). Procedural sedation is generally preferred over general anesthesia (Heart and Stroke Foundation of Canada, 2025a).

Figure 31.3 A mobile telestroke system with a high-definition camera and two-way video screen, enabling a remote stroke specialist to examine the patient and review imaging in real time with the bedside team. (credit: "10.1.15 FCC Connect2Health Task Force Beyond the Beltway Series – Jacksonville, FL (22193326376)" by Federal Communications Commission/Wikimedia Commons, Public domain)

After EVT, the nurse monitors neurologic status and blood pressure as ordered and checks the arterial access site and the limb beyond it. The nurse looks for bleeding, swelling or a growing lump at the site, and checks pulse, colour, warmth, sensation and movement of the limb. In a meta-analysis, access through the wrist (radial artery) had fewer access-site complications than access through the groin (femoral artery) (Elfil et al., 2023). Bed rest, limb positioning and how often the site is checked follow the post-procedure order or protocol (Table 31.2).

Many people first reach a hospital that cannot perform EVT. These hospitals use **telestroke**, a video assessment by a stroke physician at another centre, to decide on thrombolysis and to arrange urgent transfer to a comprehensive stroke centre (Heart and Stroke Foundation of Canada, 2022). The nurse prepares the patient and records for a rapid transfer, which is often time-critical (Figure 31.3).

The Stroke Unit

A **stroke unit** is a hospital unit in one fixed location that is set aside for people with stroke and staffed by an interprofessional team with stroke training (Heart and Stroke Foundation of Canada, 2022). Patients cared for on stroke units are more likely to be alive, living at home and independent than patients on general units (Heran et al., 2024). Compared with less organized care, stroke unit care lowered the odds of death (odds ratio 0.76) and of death or dependency (odds ratio 0.75) (Heran et al., 2024).

The benefit comes from organization rather than any single treatment. The core team includes physicians, nurses, occupational therapists, physiotherapists, speech-language pathologists, dietitians, social workers and pharmacists, with the patient and family as members of the team (Heart and Stroke Foundation of Canada, 2022). The team follows standard protocols for swallowing, mobility, prevention of complications and early rehabilitation, which are described in sections 31.5 and 31.6.

Table 31.2 Nursing care after thrombolysis (Heart and Stroke Foundation of Canada, 2022, 2025a; Hoffmann-La Roche Limited, 2024)

What to monitor	How often (as the protocol states)	Warning signs	First actions

What to monitor	How often (as the protocol states)	Warning signs	First actions
Neurologic status (stroke scale or neurologic check, level of consciousness, pupils)	Closely for the first 24 hours, at the intervals in the employer protocol	New or worse weakness, speech change, drowsiness, new headache	Stop infusion if running; call stroke physician now; prepare for urgent CT
Blood pressure and heart rate	At the protocol intervals; below 185/110 mm Hg for 24 hours	Reading at or above the ordered limit; sudden rise	Give ordered antihypertensive; recheck; report a sudden rise as a possible bleed
Lips, tongue and throat	During and for several hours after treatment	Swelling, hoarse voice, noisy breathing, trouble swallowing saliva	Stop infusion if running; call for help; airway support; ordered medicines
Bleeding sites (IV sites, gums, urine, stool, vomit)	With each set of vital signs	Oozing, blood in urine or stool, bruising or swelling	Apply pressure to compressible sites; report; avoid new punctures and intramuscular injections
Arterial access site and limb after EVT	As the post-procedure order states	Bleeding, growing lump, cool or pale limb, weak pulse, numbness	Firm pressure above the site; call for help; keep limb still
Swallowing and intake	Until a validated swallowing screen is completed	Coughing, wet voice, drooling	Keep NPO including oral medications; mouth care; request the screen

CANADIAN CONTEXT

Getting Stroke Care Across Canada

Canada's stroke systems sort hospitals by the care they can give. The CSBPR describe primary stroke centres that give thrombolysis, sometimes supported by telestroke; centres that also have acute stroke units; and comprehensive stroke centres that also provide endovascular treatment (Heart and Stroke Foundation of Canada, 2022).

Distance shapes access. A 2017 geospatial analysis of the eight provinces with available data, using 2011 census populations, found that the share of residents within a 4.5-hour road ambulance trip of a stroke centre ranged from 47.1% in Newfoundland and Labrador to 96.4% in Ontario (Eswaradass et al., 2017). Telestroke, transfer agreements and pre-notification help close these gaps.

Gaps also follow structural lines. In Ontario, First Nations people with diabetes were less likely than other Ontarians with diabetes to receive thrombolysis; the researchers set this gap in the context of colonization and marginalization and called for research on Indigenous-specific determinants of health (Kapral et al., 2020). The study was guided by the First Nations principles of OCAP® (ownership, control, access and possession) and approved by the Chiefs of Ontario Data Governance Committee (Kapral et al., 2020). Nurses in rural, remote, northern and Indigenous communities recognize stroke early, find the LKW time, check glucose and arrange rapid transfer, often by telephone or video with a stroke centre.

PRACTICE STORY

Last Known Well

Names and details are fictional; this is a composite story.

Nurse: Ama Owusu, RPN. Years in practice: 4. Setting: medical unit, Ontario.

At 0240 I went in to check Mr. Bouchard's IV. He was 74, in for a urinary tract infection, and on my midnight round he had been chatting about curling. Now he was awake and trying to tell me something, but the words came out thick. The right side of his mouth sagged. When I asked him to hold both arms up with his eyes closed, the right one drifted down to the bed.

My first thought was that he was just sleepy or delirious. Then I remembered how quickly he had talked at midnight. This was sudden, and it was on one side.

I pressed the call bell and asked the personal support worker (PSW) to get Daniel, the RN. While I waited, I checked his glucose: 6.2 mmol/L. Not low, so hypoglycemia wasn't the cause. His blood pressure was 178/96 mm Hg, higher than his usual. I asked Mr. Bouchard to nod if he understood me. He nodded. I told him I thought something was happening in his brain and that help was coming.

When Daniel arrived, I gave him the facts: "Last known well at midnight, when I spoke with him. Found at 0240 with right facial droop, right arm drift and slurred speech. Glucose 6.2. BP 178/96." Daniel looked once and said, "Call it." Our policy lets any nurse activate the in-hospital code stroke, so I called switchboard while he stayed at the bedside. I took the water jug off the table and put up a sign: NPO.

The team arrived within minutes, and he went to CT. I learned later that he had a clot in a large artery and was transferred for thrombectomy.

What stays with me is the time. If I had written "found at 0240," the team might have thought the clock started then. Midnight was the truth.

Reflect: What did the RPN's assessment add to the team's decision? Which parts of this response were within the RPN's authority, competence and context, and how would employer policy on who may activate a code stroke change what the RPN did?

31.4 Hemorrhagic Stroke

In a hemorrhagic stroke, a blood vessel breaks and blood escapes into or around the brain (Table 31.1, section 31.1). Both main types are emergencies, and both can raise intracranial pressure (ICP; section 30.4).

Intracerebral Hemorrhage

In an ICH (section 31.1), the escaped blood collects as a clot, called a hematoma, that presses on and injures the brain around it, and its added volume can raise ICP. In Canada, ICH accounts for 10% to 15% of the strokes seen in hospitals, and its mortality is much higher than that of ischemic stroke (40% compared with 15%), as the CSBPR on ICH reports (Shoamanesh et al., 2021; Figure 31.4).

Risk factors. The CSBPR lists older age, high blood pressure, ongoing anticoagulant use and an earlier small-vessel (lacunar) stroke as clinical factors that raise the risk of another ICH (Shoamanesh et al., 2021). A bleed in a lobe near the surface of the brain suggests **cerebral amyloid angiopathy**, and the team uses imaging criteria to make this diagnosis (Shoamanesh et al., 2021). In this condition, a protein called beta-amyloid builds up in the walls of small blood vessels in the outer brain and its coverings; it is a leading cause of lobar bleeds in older adults.

Manifestations and diagnostics. An ICH causes sudden deficits that look like an ischemic stroke (section 31.2). Only urgent brain imaging, with CT or magnetic resonance imaging (MRI), can tell bleeding from a clot (Shoamanesh et al., 2021). As the hematoma or the swelling around it grows, signs of rising ICP, such as a falling level of consciousness, headache and vomiting, may appear (section 30.4).

Blood pressure. The CSBPR states that blood pressure is checked on arrival in the emergency department and every 15 minutes after that. It states that lowering systolic pressure to a target below 140 mm Hg does not worsen neurologic outcomes, although clinical benefit has not been proven, and it suggests that an individual systolic target below 140 to 160 mm Hg during the first 24 to 48 hours may be reasonable (Shoamanesh et al., 2021). The nurse

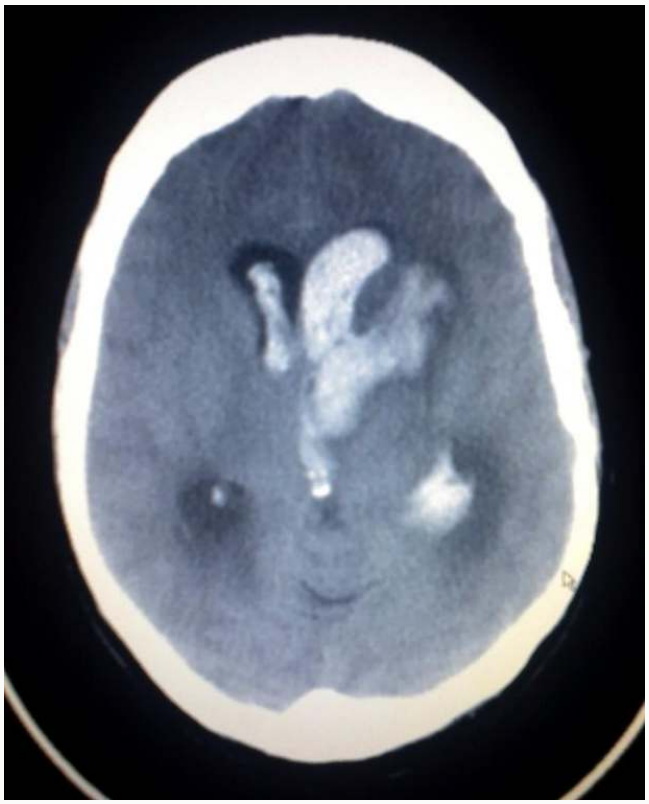

Figure 31.4 Non-contrast head CT showing an acute intracerebral hemorrhage with intraventricular extension. (credit: “Intracerebral hemorrage (CT scan)” by Glitzy queen00/Wikimedia Commons, Public domain)

measures blood pressure as often as ordered, gives antihypertensives as ordered or per protocol, and reports readings outside the target at once.

Anticoagulants. The nurse finds out early whether the patient takes an anticoagulant and when the last dose was taken (Heart and Stroke Foundation of Canada, 2022). The CSBPR states that anticoagulation is withheld in anticoagulant-related ICH and immediate reversal is considered, and that reversal should not wait for laboratory results but be based on the clinical history (Shoamanesh et al., 2021). The nurse prepares to give reversal agents as ordered without delay (section 19.7).

Ongoing care. The nurse compares each neurologic check with the last, using the Glasgow Coma Scale and pupil checks (Chapter 30), and escalates any decline at once (Chapter 6). The CSBPR recommends intermittent pneumatic compression (IPC) devices from the day of admission to prevent venous thromboembolism (VTE). It does not recommend graduated compression stockings, and it allows low-molecular-weight heparin only after 48 hours and once imaging shows the hematoma is stable (Shoamanesh et al., 2021). Corticosteroids are not recommended for raised ICP (section 30.4), and an external ventricular drain may be considered for a patient with a reduced level of consciousness and hydrocephalus (Shoamanesh et al., 2021). In the long term, the CSBPR aims to keep blood pressure consistently below 130/80 mm Hg after ICH (Shoamanesh et al., 2021).

Subarachnoid Hemorrhage

In an SAH (section 31.1), blood enters the space around the brain where cerebrospinal fluid (CSF) flows. Trauma can cause an SAH (Chapter 32), but a non-traumatic SAH is mostly caused by the rupture of a **cerebral aneurysm**, a weak, bulging area in the wall of a brain artery (Korkmaz Dilmen & Bonhomme, 2023). The CSBPR does not have a module on aneurysmal SAH, so this section draws on the 2023 guideline of the American Heart Association and American Stroke Association (AHA/ASA; Hoh et al., 2023; Figure 31.5).

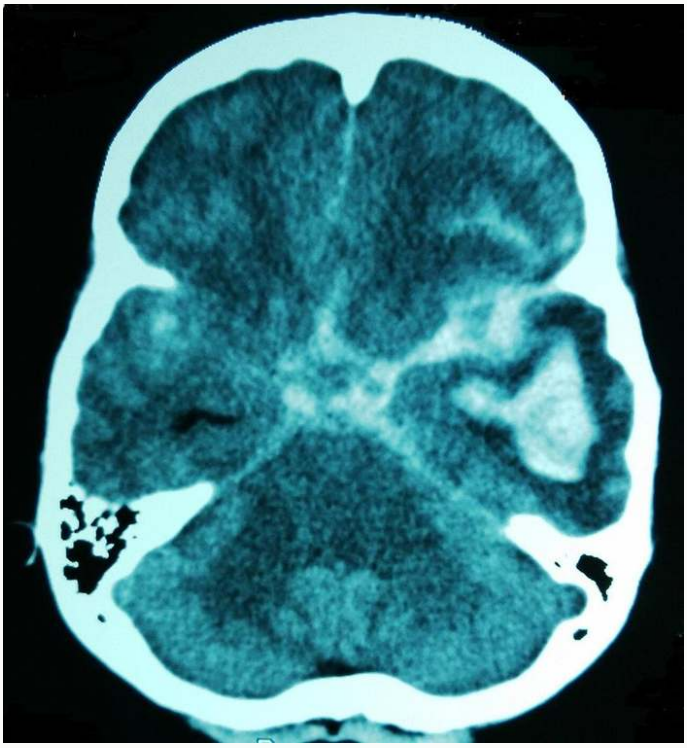

Figure 31.5 Non-contrast head CT showing acute subarachnoid hemorrhage filling the basal cisterns and left Sylvian fissure, along with a left temporal hemorrhage. (credit: "CT brain showing subarachnoid haemorrhage and left temporal haemorrhage" by Cerevisae/Wikimedia Commons, CC BY-SA 4.0)

Recognizing SAH. In an awake patient, the classic sign is a headache that begins suddenly (Hoh et al., 2023). Patients often describe it as the worst headache of their life (Korkmaz Dilmen & Bonhomme, 2023). A sudden, severe headache is a red flag that needs emergency assessment (section 30.6).

Securing the aneurysm. A ruptured aneurysm can bleed again, most often in the first 24 hours (Korkmaz Dilmen & Bonhomme, 2023). The AHA/ASA guideline recommends prompt treatment of the ruptured aneurysm, preferably within 24 hours, because early treatment lowers the risk of rebleeding (Hoh et al., 2023). In **coiling**, a catheter is threaded through an artery and small coils are placed inside the aneurysm so that blood no longer enters it. In **clipping**, a surgeon opens the skull and places a clip across the neck of the aneurysm. The guideline recommends timely transfer to experienced centres with dedicated neurocritical care units. Before the aneurysm is secured, it advises gradual lowering of very high blood pressure while strictly avoiding low pressure (Hoh et al., 2023).

Complications. The nurse watches for four complications:

- **Delayed cerebral ischemia: Delayed cerebral ischemia** (DCI) is new brain ischemia that develops days after the bleed, often linked to narrowing of brain arteries (vasospasm). One review places this risk between days 5 and 15, sometimes up to day 21 (Korkmaz Dilmen & Bonhomme, 2023). New confusion, drowsiness, weakness or speech

change suggests DCI and is reported at once. The guideline states that this monitoring needs trained nurses who can detect changes in the neurologic examination quickly (Hoh et al., 2023).

- **Hydrocephalus:** Blood can block the flow of CSF and cause hydrocephalus; an external ventricular drain may be placed (Korkmaz Dilmen & Bonhomme, 2023; section 30.4).
- **Hyponatremia:** Low sodium is a prominent feature of aneurysmal SAH. The AHA/ASA guideline names two causes: cerebral salt wasting, in which the kidneys lose sodium and water, and the syndrome of inappropriate antidiuretic hormone (SIADH; Hoh et al., 2023; section 3.4). Sodium loss through the kidneys can lower blood volume, and low blood volume is associated with DCI (Hoh et al., 2023). For this reason, cerebral salt wasting is treated by replacing sodium and fluid rather than by restricting fluid (Korkmaz Dilmen & Bonhomme, 2023). The nurse tracks intake, output and sodium results and reports a falling sodium.
- **Rebleeding:** A sudden new headache or a drop in level of consciousness before the aneurysm is secured needs immediate escalation.

Medications. The AHA/ASA guideline states that early **nimodipine**, given by the enteral route (by mouth or feeding tube), helps prevent DCI and improves outcomes (Hoh et al., 2023). It does not recommend routine extra fluids or raised blood pressure to prevent DCI (Hoh et al., 2023). If the patient cannot swallow safely, the nurse asks how it is to be given rather than omitting it.

31.5 Stroke Unit Care

Section 31.3 explained why organized stroke unit care saves lives; this section describes the nursing care on the unit. The CSBPR asks the team to build an individual plan for nutrition, oral care, mobility and continence for every patient, to reduce the risk of urinary tract infection, aspiration pneumonia and VTE, and to begin planning for discharge from admission (Heart and Stroke Foundation of Canada, 2022).

Swallowing, Nutrition and Hydration

Dysphagia, or difficulty swallowing, is common after stroke (section 24.3). **Aspiration** is the entry of food, fluid, saliva or stomach contents into the airway below the vocal cords. A patient may aspirate without coughing, without a wet voice and without reporting a problem, and aspiration can lead to pneumonia (Heart and Stroke Foundation of Canada, 2022; section 13.2).

Screening before anything by mouth. The CSBPR states that a trained professional should screen swallowing with a valid tool before the patient takes anything by mouth, including medications, food and fluids, and that the screen should happen as early as possible, ideally on the day of admission (Heart and Stroke Foundation of Canada, 2022). This is **dysphagia screening**. The employer chooses the screening tool and trains the staff who use it. The CSBPR rationale cites a large trial in which pneumonia developed in 10.0% of patients who failed the swallowing screen and 1.5% of those who passed (Heart and Stroke Foundation of Canada, 2022). Until then, the patient stays NPO; the nurse gives mouth care and reports the need for another route for essential medications.

Assessment and the plan. A failed screen leads to referral to a speech-language pathologist (SLP), an occupational therapist, a dietitian or another dysphagia clinician, who sets an individual plan for diet and therapy (Heart and Stroke Foundation of Canada, 2022, 2025c). The nurse follows the plan at every meal: the diet texture and fluid thickness (section 24.3), sitting upright, supervision and pacing. If eating by mouth is unsafe or not enough, the CSBPR states that enteral feeding, for example through a nasogastric tube, is considered with the patient, family or substitute decision-maker, usually within the first 3 days (Heart and Stroke Foundation of Canada, 2022). The nurse also watches intake and hydration, since dehydration raises the risk of VTE (Heart and Stroke Foundation of Canada, 2022).

Medications. Once the patient may swallow, medications are given in the form the plan allows. The nurse checks with the pharmacist before crushing any tablet, because extended-release and enteric-coated products must not be crushed (section 24.3).

Oral care. The CSBPR calls for an assessment of the mouth and teeth on or shortly after admission, a check that the patient can use dentures safely, and oral care according to Canadian Dental Association guidance, ideally after meals and at bedtime (Heart and Stroke Foundation of Canada, 2022). Families who bring food from home need to know the plan, because a well-meant meal can be the wrong texture.

Positioning, Mobility and Prevention of Complications

Early mobilization. The 2025 CSBPR rehabilitation module advises against very early, high-intensity mobilization in the first 24 hours; once the patient is medically stable, mobilization should start, ideally 24 to 48 hours after the stroke, with caution (Heart and Stroke Foundation of Canada, 2025b). The acute module adds that early prolonged out-of-bed activity in the first 24 to 48 hours, especially after a severe stroke, is not recommended. It lists cautions such as a recent arterial puncture for a procedure, an unstable condition, low oxygen saturation and a leg fracture (Heart and Stroke Foundation of Canada, 2022).

The hemiplegic shoulder. A **hemiplegic shoulder** is the shoulder on the weak side, which can partly slip out of its joint and become painful. Shoulder pain after stroke affects roughly 22% to 47% of people (Heart and Stroke Foundation of Canada, 2025c). The CSBPR recommends supporting and positioning the arm at rest; never pulling on the weak arm; protecting it during transfers; avoiding overhead pulleys; limiting passive movement above 90 degrees unless the shoulder blade and arm are positioned for it; and teaching staff, the patient and family how to handle the arm. Slings are used only in the flaccid stage when no other support is possible (Heart and Stroke Foundation of Canada, 2025c).

Venous thromboembolism. Every patient is assessed for VTE risk. For high-risk patients, the CSBPR recommends thigh-high IPC or an anticoagulant for prophylaxis from the day of admission unless contraindicated. IPC stops when the patient walks independently, at discharge, if adverse effects occur or at 30 days, whichever comes first; graduated compression stockings are not recommended (Heart and Stroke Foundation of Canada, 2022). The nurse checks the skin under the sleeves (Chapter 7; section 19.6).

Skin, continence and bowels. The team assesses skin breakdown risk on admission (Heart and Stroke Foundation of Canada, 2022; Chapter 35). Indwelling urinary catheters are used with caution, reassessed daily and removed as soon as possible. Patients are screened for incontinence, retention and constipation; a portable bladder scanner measures urine left after voiding; and timed and prompted toileting and a bowel program are used as needed (Heart and Stroke Foundation of Canada, 2022).

Temperature, glucose and oxygen. The CSBPR recommends checking temperature along with the other vital signs, ideally every 4 hours during the first 48 hours. A temperature above 37.5 °C prompts closer monitoring, cooling, a search for infection such as pneumonia or urinary tract infection, and treatment as ordered (Heart and Stroke Foundation of Canada, 2022). Low blood glucose is corrected immediately using local protocols, and high glucose is treated per local protocols (Heart and Stroke Foundation of Canada, 2022; Chapter 22). Supplemental oxygen is not needed when oxygen saturation is normal (Heart and Stroke Foundation of Canada, 2022); it is given as ordered when saturation falls (Chapter 12).

Communication, Cognition and Mood

Aphasia (section 31.2) can affect speaking, understanding, reading and writing. In **expressive aphasia**, the person understands more than they can say and struggles to find or form words. In **receptive aphasia**, the person has trouble understanding spoken or written language and may speak fluently but without clear meaning. **Dysarthria** is different: language is intact, but weak or poorly coordinated speech muscles make speech slurred. Between 21% and 38% of people are aphasic in the early days after stroke (Heart and Stroke Foundation of Canada, 2025c).

The CSBPR states that every person with stroke needs a screen for communication problems, that an SLP should assess those with suspected problems, and that staff and families should be trained in supported conversation (Heart and Stroke Foundation of Canada, 2025c). Practical strategies:

- Reduce noise and face the person; one person speaks at a time.
- Use short sentences and questions with a yes or no answer, and allow time.
- Add gestures, writing, pictures or a tablet, and confirm what the person meant.
- Speak to the person as an adult, never as if they were absent.

Aphasia alone does not mean that a person lacks capacity to consent. Capacity is assessed for each decision, with communication supports in place (Chapter 1).

Unilateral neglect (section 31.2) usually affects the left side after a stroke in the right hemisphere. The patient may eat food from only half the tray or bump into door frames. The CSBPR recommends early screening of everyone with stroke for visual-perceptual

problems, education for the person and family on safety, and compensatory strategies such as cues and changes to the surroundings; visual scanning training is one therapy option (Heart and Stroke Foundation of Canada, 2025c). On the unit, the nurse cues the patient to turn the head and scan, checks the neglected side of the body for injury, and keeps the call bell where the patient can find it. The CSBPR also asks the team to screen for vascular cognitive impairment when indicated; delirium is covered in Chapter 8 (Heart and Stroke Foundation of Canada, 2022).

Mood and fatigue. About one-third of people show symptoms of depression at some point after a stroke (Heart and Stroke Foundation of Canada, 2025d). **Post-stroke depression** is depression that develops after a stroke. The CSBPR states that everyone with stroke should be screened for it if medically appropriate, by trained professionals using a validated tool, especially at transition points such as moving to rehabilitation or going home. Treatment can include psychological therapy, an antidepressant and supervised exercise (Heart and Stroke Foundation of Canada, 2025d). The 2025 module also addresses sleep and post-stroke fatigue, so the nurse asks about tiredness and plans rest between therapies (Heart and Stroke Foundation of Canada, 2025d). Families are part of the core team, and they too are at risk of depression (Heart and Stroke Foundation of Canada, 2022, 2025d).

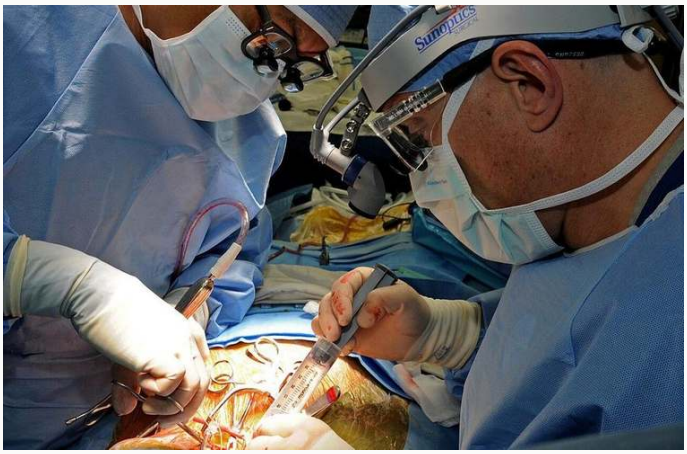

Figure 31.6 Vascular surgeons performing a carotid endarterectomy to remove atherosclerotic plaque from the internal carotid artery for secondary stroke prevention. (credit: "David Grant USAF Medical Center 110523-F-ML202-008" by Staff Sgt. Liliana Moreno/U.S. Air Force, Public domain)

Secondary Prevention

Secondary prevention is care that lowers the risk of another stroke after a stroke or TIA. The CSBPR states that people seen within 48 hours of new stroke or TIA symptoms are at the highest risk of another stroke and should be sent immediately to an emergency department that can provide stroke care; those seen later should have a full evaluation by a clinician with stroke expertise as soon as possible (Heart and Stroke Foundation of Canada, 2022; Figure 31.6).

Table 31.3 summarizes the targets in the CSBPR secondary prevention module (Heart and Stroke Foundation of Canada, 2020). **Antiplatelet therapy** uses medicines that keep platelets from clumping to form clots. After an ischemic stroke or TIA, long-term antiplatelet therapy is recommended unless the person needs an anticoagulant. For a high-risk TIA or minor stroke, two antiplatelets are given together for a short time and then reduced to one. People with atrial fibrillation (section 16.6) receive an oral anticoagulant instead, with a direct oral anticoagulant preferred over warfarin for most patients. The CSBPR states that the best time to start it has not been well defined; by expert consensus, timing ranges from within 1 day after a TIA to 12 to 14 days after a severe stroke (Heart and Stroke Foundation of Canada, 2020). The CSBPR secondary prevention module dates from 2020, while Hypertension Canada updated its guideline in 2025 (Chapter 19), so the nurse follows the target the team sets for each patient.

Table 31.3 Secondary prevention after stroke or TIA (Heart and Stroke Foundation of Canada, 2020; original wording)

Risk factor	Target or recommendation as the CSBPR states it	Medicines (named only)	Teaching
Blood pressure	Consistently lower than 140/90 mm Hg after ischemic stroke or TIA (2020 module); systolic consistently lower than 130 mm Hg after a small subcortical stroke; consistently lower than 130/80 mm Hg with diabetes and after ICH; follow the target the team sets	ACE inhibitor plus a thiazide or thiazide-like diuretic; others per Hypertension Canada	Home blood pressure checks; take medicines daily even when feeling well
Lipids	Low-density lipoprotein (LDL) cholesterol below 1.8 mmol/L	A statin, such as atorvastatin; ezetimibe may be added	Take the statin as prescribed; report muscle pain
Clots (no atrial fibrillation)	Long-term antiplatelet therapy; two antiplatelets for a short period after high-risk TIA or minor stroke	Acetylsalicylic acid (ASA), clopidogrel; ticagrelor with ASA as a short-term option	Do not stop without advice; report bleeding or black stools

Risk factor	Target or recommendation as the CSBPR states it	Medicines (named only)	Teaching
Atrial fibrillation	Oral anticoagulation; direct oral anticoagulant preferred over warfarin	Apixaban or another direct oral anticoagulant; warfarin	Never double or skip doses; report bleeding; carry a medication list
Smoking	Status asked and recorded in every setting; medicine plus counselling to quit	Nicotine replacement therapy, varenicline, bupropion	Avoid second-hand smoke; ask for quit support
Diet and weight	Mediterranean-type or DASH (Dietary Approaches to Stop Hypertension) eating pattern; limit sodium to 2,000 mg or less per day	None	Read labels for sodium; healthy weight targets differ across populations
Physical activity	At least 150 minutes per week of aerobic activity, 4 to 7 days a week, intensity individualized	None	Start with what is safe and build up with the rehabilitation team
Alcohol, drugs and hormones	Avoid heavy alcohol use; stop cocaine and amphetamines; estrogen-containing contraception or hormone therapy discouraged	None	Ask about safer contraception options

PATIENT EDUCATION

Stroke Warning Signs and Preventing Another Stroke

Before discharge, the nurse teaches the patient and family two things: how to spot a new stroke and how to prevent one.

- **Know FAST:** Heart & Stroke's FAST message asks: Face — is it drooping? Arms — can you raise both? Speech — is it slurred or jumbled? Time — to call 9-1-1 right away (Heart and Stroke Foundation of Canada, 2023). Section 31.2 describes the other signs.
- **Call, don't drive:** Do not drive to the hospital; the ambulance goes to a hospital that provides urgent stroke care (Heart and Stroke Foundation of Canada, n.d.-c). Note the time the signs started or the person was last seen well.
- **Treat a TIA as urgent:** Signs that go away still need emergency care.
- **Take medicines every day:** Antiplatelets, anticoagulants, statins and blood pressure medicines protect the brain only if taken. Never stop one without speaking to the prescriber.
- **Know your numbers:** Learn your blood pressure target and how to check it at home.
- **Build habits:** Stop smoking, limit sodium, be active most days and avoid heavy drinking (Heart and Stroke Foundation of Canada, 2020).
- **Keep follow-up visits:** See the primary care provider, ideally within the first month after discharge (Heart and Stroke Foundation of Canada, 2025d).

The nurse uses teach-back and gives written material in the person's preferred language, with pictures for people with aphasia.

CLINICAL JUDGMENT

Coughing at Lunch

Names and details are fictional; this is a composite story.

Tomasz Kowalczyk, 66, is on day 2 after a right hemisphere ischemic stroke with left arm weakness. He passed the nurse's swallowing screen yesterday and is eating a regular diet. At lunch, the nurse hears him cough three times while drinking tea. His voice now sounds wet and gurgly.

- **Recognize cues:** Coughing with fluids and a wet voice after swallowing. He is pocketing food in his left cheek. His oxygen saturation is 95%, unchanged; his temperature is 36.9 °C.
- **Analyze cues:** A screen is a first check, not a full assessment. These cues suggest that he is not handling thin fluids safely, and left neglect may stop him noticing food on his left side.
- **Prioritize hypotheses:** Aspiration of thin fluids is the main concern. Pneumonia has not developed yet, but the risk is high.
- **Generate solutions:** Stop oral intake for now, clear his mouth, keep him upright, inform the team and request an SLP assessment as policy directs.
- **Take action:** The nurse stops the meal, suctions the mouth per policy, sits him upright and checks his breathing. Using SBAR (Chapter 6), the nurse reports to the RN in charge and the physician, and refers him to the SLP. The nurse also asks the

pharmacist and prescriber how his noon medicines should be given while he is NPO. Mouth care removes the pocketed food.

- **Evaluate outcomes:** That afternoon, the SLP assesses him and recommends thickened fluids, supervised meals and cueing to check his left cheek. The nurse updates the care plan and the bedside sign. Over the next 48 hours his temperature, breathing and saturation stay normal, and he clears his left cheek when cued.

31.6 Rehabilitation, Transitions and Living After Stroke

Recovery after stroke continues long after the patient leaves the acute unit. In 2025, Heart & Stroke reorganized its CSBPR rehabilitation recommendations into three parts: planning rehabilitation, delivering it, and supporting activity and community participation (Heart and Stroke Foundation of Canada, 2025b, 2025c, 2025d). This section summarizes what the nurse needs to know from them.

Rehabilitation

Rehabilitation is the coordinated, goal-directed care that helps a person regain function and take part in daily life after illness or injury. The CSBPR states that every person with stroke should receive rehabilitation as early as possible once medically stable and able to take part (Heart and Stroke Foundation of Canada, 2025b). The plan is person-centred, decisions are shared, and goals are culturally appropriate and agreed on by the person (Heart and Stroke Foundation of Canada, 2025b). Rehabilitation needs are assessed early: the acute module asks rehabilitation professionals to assess each patient, ideally within 48 hours of admission, and to assess rehabilitation needs within the first 72 hours (Heart and Stroke Foundation of Canada, 2022). For inpatient rehabilitation, the CSBPR recommends direct, task-specific therapy for three hours a day, five days a week, once the person is medically and neurologically stable. Therapy uses repeated, demanding tasks that challenge the person (Heart and Stroke Foundation of Canada, 2025b).

The interdisciplinary team includes physicians, nurses, physiotherapists, occupational therapists, speech-language pathologists, dietitians, social workers and pharmacists, with the patient and family as members (Heart and Stroke Foundation of Canada, 2022). The CSBPR asks the team to help the person practise therapy skills in daily routines (Heart and Stroke Foundation of Canada, 2025b). Nurses do this all day: a patient who learned a safe transfer in physiotherapy uses the same steps to reach the toilet with the nurse, and a patient practising dressing with the occupational therapist dresses that way each morning. The same is true of the swallowing plan, communication strategies and toileting schedules: each works only if every shift follows it. Nurses also screen for depression at transition points, such as transfer to rehabilitation or discharge home (Heart and Stroke Foundation of Canada, 2025d). Table 31.4 links common effects of stroke to nursing strategies and team members.

Rehabilitation can also take place in outpatient clinics, at home, in long-term care and by video. The 2025 module includes virtual rehabilitation, which can extend therapy, education and transition planning to people far from a stroke centre (Heart and Stroke Foundation of Canada, 2025b). In **early supported discharge**, a rehabilitation team continues therapy at home so that a person with a mild or moderate stroke can leave hospital sooner; the CSBPR states that it should be considered where appropriate and that services should start within 48 hours of discharge from acute care (Heart and Stroke Foundation of Canada, 2025b). When function declines months or years later, the person should be able to re-enter rehabilitation (Heart and Stroke Foundation of Canada, 2025b, 2025d).

Table 31.4 Common effects of stroke and nursing strategies (Heart and Stroke Foundation of Canada, 2022, 2025c, 2025d; original wording)

Effect	What the nurse sees	Nursing strategies	Team member
Hemiparesis	Weakness of the arm and leg on one side; unsteady standing	Safe transfers that follow the therapy plan; fall prevention; position the weak limbs	Physiotherapist, occupational therapist
Hemiplegic shoulder	Painful or partly dislocated shoulder on the weak side	Support the arm at rest; never pull on it; no overhead pulleys; teach the family	Physiotherapist, occupational therapist
Dysphagia	Coughing or a wet voice with eating; pocketed food; weight loss	NPO until screened; follow the diet and fluid plan; upright for meals; mouth care	SLP, dietitian

Effect	What the nurse sees	Nursing strategies	Team member
Aphasia	Trouble finding words or understanding speech	Quiet setting, short sentences, yes or no questions, pictures, time	SLP
Unilateral neglect	Ignores one side of space or of the body	Cue scanning; check the neglected side for injury; keep the call bell within reach	Occupational therapist
Bladder and bowel changes	Incontinence, retention, constipation	Bladder scan, timed toileting, bowel program; remove catheters early	Trained continence staff, physician
Depression and fatigue	Low mood, tearfulness, loss of interest, tiredness	Screen with a validated tool; plan rest; refer early	Physician, psychologist, social worker

Going Home and Living After Stroke

Transitions of care are moves from one setting or team to another, such as from the stroke unit to rehabilitation, home or long-term care. The CSBPR states that transition planning begins at admission (Heart and Stroke Foundation of Canada, 2022). Families take part in transition planning meetings, and the CSBPR suggests a review with the primary care provider, ideally within the first month after discharge (Heart and Stroke Foundation of Canada, 2025b, 2025d). The nurse's handover includes the swallowing plan, mobility, communication needs, medicines and the goals set with the person. Before discharge, the nurse checks that the patient and family know the medicines, the follow-up appointments, whom to call with questions and when to call 9-1-1.

Caregivers. The CSBPR states that people with stroke and their families should be supported through every transition with psychosocial support, education and skills training (Heart and Stroke Foundation of Canada, 2025b). **Caregiver strain** is the physical, emotional and financial stress of caring for someone. The team assesses the caregiver's willingness and ability to learn care skills, how they are coping, and needs such as money, housing and transportation (Heart and Stroke Foundation of Canada, 2025b). Without enough support, caregivers may develop burnout, depression or anxiety. The evidence the CSBPR cites found depressive symptoms in about 40% of stroke caregivers and high burden in 35% of spouses six months after the stroke (Heart and Stroke Foundation of Canada, 2025b). The nurse teaches skills hands-on before discharge, such as transfers, safe feeding and medicine routines, and shares information about peer and caregiver support groups (Heart and Stroke Foundation of Canada, 2025b).

Driving. The CSBPR advises people not to drive for a minimum of one month after a stroke, consistent with national medical standards for drivers. After a TIA, the person does not drive until a full neurologic assessment shows no remaining loss of function and no clear risk that symptoms will suddenly return (Heart and Stroke Foundation of Canada, 2025d). Fitness to drive is assessed for vision, neglect, movement and thinking, sometimes with an on-road test, and provincial and territorial law governs reporting and licensing (Heart and Stroke Foundation of Canada, 2025d). In Ontario, physicians and nurse practitioners must report certain medical conditions to the Ministry of Transportation (section 30.5). People who cannot drive need help with other transportation and support for the loss of independence.

Work and community. The CSBPR asks the team to screen early for work, school and volunteer roles, to support a gradual return with accommodations, and to refer to vocational services and review finances and benefits (Heart and Stroke Foundation of Canada, 2025d). After discharge, primary care and community teams keep following the person. The CSBPR asks them to track recovery, to screen for changes in thinking, mood and anxiety compared with before the stroke, and to keep secondary prevention on track in every setting, including long-term care. People whose function declines should receive targeted help even years later, and everyone with stroke should have access to evidence-based community exercise programs (Heart and Stroke Foundation of Canada, 2025d). The CSBPR also addresses leisure, relationships and sexuality (Heart and Stroke Foundation of Canada, 2025d). The nurse invites questions about intimacy rather than waiting for the person to raise them.

Equity. The 2025 module states that equity in access to services must be considered at every stage of recovery (Heart and Stroke Foundation of Canada, 2025b). Rural and remote communities may lack local rehabilitation, so virtual rehabilitation and travel support matter. People who speak French or another language need professional interpreters and translated materials. Care with First Nations, Inuit and Métis people is distinctions-based and culturally safe, and it involves community health services and family (Chapter 2; section 31.3).

Severe Stroke and Palliative Care

Some strokes are catastrophic, or occur in people who already have serious illness. The CSBPR recommends a palliative approach for these patients (Heart and Stroke Foundation of Canada, 2022). The team discusses with the patient, if able, and the substitute decision-maker the diagnosis, prognosis, values and wishes, and whether the aim of care should be comfort or a longer life. These conversations continue as the situation changes and are documented (Heart and Stroke Foundation of Canada, 2022). Decisions about feeding tubes, intravenous fluids and other life-prolonging treatments consider the person's prior wishes and best interests (Heart and Stroke Foundation of Canada, 2022). The nurse manages pain, secretions, mouth and eye care, and supports the family, including after death (Heart and Stroke Foundation of Canada, 2022). For people living in the community after stroke, the CSBPR recommends revisiting the person's goals of care and advance care planning at intervals, for example yearly, and whenever health changes; these plans may name a substitute decision-maker and must follow provincial or territorial law (Heart and Stroke Foundation of Canada, 2025d). Goals of care and end-of-life care are covered in Chapter 10.

SCOPE IN PRACTICE

Stroke Care and Who Does What

The College of Nurses of Ontario's (CNO's) Scope of Practice standard asks every nurse to consider **authority**, **competence** and **context** (section 1.3).

- **Every nurse:** Any nurse who sees new stroke signs, such as a facial droop, arm drift or new trouble speaking, acts at once. The nurse notes the time the patient was last known well, checks glucose and calls for help per policy (section 31.2). No nurse waits for someone else to notice.
- **Dysphagia screening:** RNs and RPNs can screen swallowing when the employer authorizes it and they have completed the training for the employer's validated tool. A nurse who has not been trained keeps the patient NPO and finds a trained colleague.
- **Thrombolysis and titrated infusions:** Many employers limit giving thrombolytics and titrating intravenous antihypertensive infusions to RNs with specialized education. This is an employer policy based on context and competence, not a CNO rule.
- **Changing needs:** When a patient's condition changes or becomes less predictable, the RPN consults the RN and works with the team; the RN may take over parts of care as needs change.
- **Teaching and transitions:** Both RNs and RPNs teach patients and families and contribute to transition planning within their competence.

Employer policy and the province or territory matter. In other provinces, practical nurses (licensed practical nurses in many provinces) follow their own regulator's standards.

LIFESPAN CONSIDERATIONS

Stroke in Older Adults

Older adults. The risk of stroke rises with age (section 31.1). Atrial fibrillation becomes much more common with age (section 16.6), and lobar bleeds from cerebral amyloid angiopathy are a concern in this group (section 31.4). Several points need extra attention:

- **Delirium and baseline:** A new stroke and delirium can both cause sudden confusion. The nurse asks the family about the person's usual thinking and reports any change (Chapter 8).
- **Swallowing and nutrition:** Older adults may already have poor teeth, dentures that fit badly or low weight. The nurse checks dentures and weight and follows the swallowing plan.
- **Medicines:** Antithrombotic, blood pressure and statin therapy add to existing medicines. The nurse reviews the full list with the pharmacist and watches for dizziness, falls and bleeding.
- **Caregivers:** The caregiver is often an older spouse with health problems of their own. The team assesses the caregiver's capacity and needs before discharge.
- **Goals:** Recovery is still possible in later life. Rehabilitation goals are set with the person, not decided by age.

Younger adults. Stroke also occurs in younger adults, and the team may look for less common causes. Return to work, parenting and driving are often central goals.

Chapter 31 Summary

Introduction

- Much of the harm from stroke can be limited by fast treatment and by preventing complications, and nurses are often the first to see new signs.
- The chapter follows the Canadian Stroke Best Practice Recommendations and builds on the scope, CJMM, deterioration and neurologic assessment content of earlier chapters.

31.1 Understanding Stroke

- Ischemic strokes (thrombotic, embolic or small vessel) are caused by blocked arteries; hemorrhagic strokes (intracerebral or subarachnoid) are caused by bleeding.
- A TIA causes stroke signs that resolve fully, usually within an hour; it is a warning that calls for urgent assessment.
- The penumbra around the ischemic core can recover if blood flow returns in time; "time is brain."
- Heart & Stroke reports more than 108,000 strokes a year in Canada; high blood pressure is the most important modifiable risk factor.
- Women, First Nations people and rural and remote communities face particular risks and access gaps, shaped by structural causes such as colonization and distance from services.

31.2 Recognizing Stroke and Code Stroke

- FAST, as Heart & Stroke presents it: Face: is it drooping? Arms: can you raise both? Speech: is it slurred or jumbled? Time: to call 9-1-1. Other sudden signs include vision changes, severe headache, one-sided numbness and balance problems.
- Stroke causes weakness on the opposite side of the body; aphasia is typical of left hemisphere and neglect of right hemisphere strokes.
- Stroke mimics are common; glucose is checked early, but every sudden deficit is treated as a stroke until the team rules it out.
- Last known well, not the time signs were found, guides treatment; paramedics pre-notify and stroke centres run a code stroke with immediate CT and CTA.
- In-hospital strokes have had longer delays; the nurse acts at once as policy directs, and patients stay NPO, including oral medications, until a validated swallowing screen.

31.3 Hyperacute Treatment

- The CSBPR recommend thrombolysis with alteplase or tenecteplase for eligible patients with disabling ischemic stroke within 4.5 hours, with a median door-to-needle target of 30 minutes or less.
- Blood pressure is kept below 185/110 mm Hg before, during and for 24 hours after thrombolysis; monitoring frequency follows the employer protocol.
- Neurologic decline, a sudden rise in blood pressure or a new headache suggests intracranial hemorrhage; lip or tongue swelling suggests orolingual angioedema; both call for stopping the infusion and urgent help.
- Endovascular thrombectomy treats large vessel occlusions up to 24 hours from last known well in selected patients; the nurse checks the access site and limb.
- Organized stroke unit care by an interprofessional team improves survival and independence.

31.4 Hemorrhagic Stroke

- Intracerebral hemorrhage is bleeding into brain tissue; in Canada it accounts for 10% to 15% of hospital stroke cases and has higher mortality than ischemic stroke.
- The CSBPR checks blood pressure every 15 minutes at first and states that lowering systolic pressure below 140 mm Hg does not worsen outcomes; the long-term target is below 130/80 mm Hg.

- In anticoagulant-related ICH, the anticoagulant is withheld and immediate reversal is considered without waiting for laboratory results (section 19.7).
- Aneurysmal subarachnoid hemorrhage typically starts with a sudden, severe headache; the aneurysm is secured promptly by coiling or clipping.
- After SAH, the nurse watches for delayed cerebral ischemia, hydrocephalus, hyponatremia and rebleeding; enteral nimodipine helps prevent delayed cerebral ischemia.

31.5 Stroke Unit Care

- Nothing is given by mouth, including medications, until a trained professional screens swallowing with a valid tool; a failed screen leads to SLP assessment.
- The CSBPR advises against very early, high-intensity mobilization in the first 24 hours; mobilization begins once the patient is stable.
- The hemiplegic shoulder is supported and never pulled; high-risk patients receive IPC or anticoagulant prophylaxis, and compression stockings are not used.
- Aphasia calls for quiet, short questions, visual supports and time; all patients are screened for communication problems and for depression.
- Secondary prevention targets blood pressure, LDL cholesterol below 1.8 mmol/L, antithrombotic therapy, smoking, diet and activity; a TIA within 48 hours needs immediate emergency assessment.

31.6 Rehabilitation, Transitions and Living After Stroke

- Rehabilitation starts as early as the person is medically stable, with person-centred, culturally appropriate goals.
- Nurses help patients practise therapy skills in daily care.
- Caregivers need education, hands-on skills training, assessment of their own needs and links to support groups.
- The CSBPR advises no driving for a minimum of one month after a stroke, followed by an assessment of fitness to drive.
- After a catastrophic stroke, the team uses a palliative approach and holds ongoing goals-of-care discussions with the patient or substitute decision-maker.

Key Terms (43)

antiplatelet therapy: Medicines, such as ASA or clopidogrel, that keep platelets from clumping to form clots.

aphasia: A disorder of language that affects speaking, understanding, reading or writing.

aspiration: The entry of food, fluid, saliva or stomach contents into the airway below the vocal cords.

caregiver strain: The physical, emotional and financial stress of caring for someone.

cerebral amyloid angiopathy: A condition in which a protein called beta-amyloid builds up in the walls of small blood vessels in the outer brain and its coverings; a leading cause of bleeds in the outer lobes of the brain in older adults.

cerebral aneurysm: A weak, bulging area in the wall of a brain artery that can rupture and bleed.

clipping: Surgery in which the skull is opened and a clip is placed across the neck of an aneurysm.

code stroke: A hospital emergency process that brings the stroke team, imaging and laboratory together at once for a person with suspected acute stroke.

coiling: An endovascular treatment in which a catheter places small coils inside an aneurysm so that blood no longer enters it.

CT angiography (CTA): CT imaging with contrast dye that shows the arteries of the neck and brain and where an artery is blocked.

delayed cerebral ischemia: New brain ischemia that develops days after an aneurysmal subarachnoid hemorrhage, often linked to narrowing of brain arteries.

door-to-needle time: The time from hospital arrival to the start of thrombolysis.

dysarthria: Slurred or unclear speech caused by weak or poorly coordinated speech muscles, with language itself intact.

dysphagia screening: A brief check of swallowing safety, done by a trained professional with a valid tool before a patient with stroke takes anything by mouth.

early supported discharge: Rehabilitation provided at home by a specialized team so that a person with a mild or moderate stroke can leave hospital sooner.

endovascular thrombectomy (EVT): Removal of a clot from a large brain artery with a catheter threaded from an artery in the groin or wrist.

expressive aphasia: Aphasia in which the person understands more than they can say and struggles to find or form words.

FAST: Heart & Stroke's memory aid for the most common stroke signs: Face: is it drooping? Arms: can you raise both? Speech: is it slurred or jumbled? Time: to call 9-1-1.

hemiparesis: Weakness of the face, arm or leg on one side of the body.

hemiplegic shoulder: The shoulder on the weak side after a stroke, which can partly dislocate and become painful.

hemorrhagic stroke: A stroke caused by a blood vessel that ruptures and bleeds into or around the brain.

intracerebral hemorrhage (ICH): Bleeding into the brain tissue itself that is not caused by trauma.

ischemic core: The central area of an ischemic stroke, where blood flow is lowest and damage quickly becomes permanent.

ischemic stroke: A stroke in which a blocked artery deprives part of the brain, spinal cord or retina of blood until cells die.

large vessel occlusion (LVO): A blockage of a major brain artery, which may be treated with endovascular thrombectomy.

last known well (LKW): The last time a person was known to be at their usual self without the new stroke signs; used to time treatment when onset was not witnessed.

neglect: A disorder in which a person does not attend to one side of space or of their own body, most often the left side after a right hemisphere stroke.

nimodipine: A medicine given by the enteral route after aneurysmal subarachnoid hemorrhage to help prevent delayed cerebral ischemia.

orolingual angioedema: Swelling of the lips, tongue or throat that can follow thrombolysis and threaten the airway.

penumbra: Brain tissue around the ischemic core that has stopped working but can recover if blood flow returns in time.

post-stroke depression: Depression that develops after a stroke; about one-third of people show symptoms at some point.

receptive aphasia: Aphasia in which the person has trouble understanding spoken or written language.

rehabilitation: Coordinated, goal-directed care that helps a person regain function and take part in daily life after illness or injury.

secondary prevention: Care that lowers the risk of another stroke after a stroke or transient ischemic attack.

stroke: A sudden loss of brain, spinal cord or retinal function caused by a blocked or bleeding blood vessel, with evidence of injury on imaging.

stroke mimic: A condition, such as low blood glucose, seizure or migraine, that causes sudden stroke-like signs but is not a stroke.

stroke unit: A hospital unit in one fixed location, set aside for people with stroke, where a stroke-trained interprofessional team provides care.

subarachnoid hemorrhage (SAH): Bleeding into the space between the brain and its thin covering membranes, often from a ruptured aneurysm.

symptomatic intracranial hemorrhage: Bleeding in the brain that worsens the person's condition, the most serious complication of thrombolysis.

telestroke: A video assessment by a stroke physician at another centre to support treatment and transfer decisions.

thrombolysis: Treatment with an intravenous medicine, such as alteplase or tenecteplase, that dissolves a clot blocking an artery.

transient ischemic attack (TIA): A brief episode of stroke-like symptoms caused by ischemia, with no infarct on imaging; symptoms resolve within 24 hours, usually within an hour.

transitions of care: Moves of a patient from one setting or team to another, such as from the stroke unit to rehabilitation or home.

Licensure Review & Clinical Judgment Questions (40)

Questions tagged **[Core]** apply to all nursing students (NCLEX-RN, REx-PN, and CPNRE). Questions tagged **[RN]** draw on *Going Deeper* content.

Case: Edward Tran (Questions 1–4): Edward Tran, 68, is on a medical unit in Ontario with community-acquired pneumonia. He has hypertension and takes apixaban for atrial fibrillation. At 0100 the RPN found him awake, talking clearly and asking for a blanket. At 0300 the RPN finds him sitting up and unable to lift his left arm. His speech is slurred, and the left side of his mouth droops. He is alert and follows simple requests with his right hand. Blood pressure is 182/98 mm Hg, heart rate 94 and irregular, and oxygen saturation 95% on room air.

1. [CORE] Which time should the RPN report to the team as Mr. Tran's last known well?

a. 0300, because that is when the RPN first saw his weakness and slurred speech on rounds.

b. 0100, because that is the last time he was seen at his usual self without the new signs.

c. The time of his last dose of apixaban, because that time decides whether he may receive thrombolysis.

d. The time he was admitted to hospital, because his pneumonia may have caused the new deficits.

Answer: b — Last known well is the last time the person was known to be at baseline without the new signs (section 31.2, The First Hour). He was talking clearly at 0100. Option a is the time the signs were found, not when he was last well; using it would make the treatment window look longer than it is. Option c is important information the team also needs, but it is not the LKW time. Option d confuses the reason for admission with the onset of new signs.

2. [CORE] While help is on the way, which action should the RPN take?

a. Give Mr. Tran a sip of water so that he can take his scheduled oral antibiotic on time.

b. Lower the head of the bed flat and recheck his arm strength in 30 minutes to see whether it improves.

c. Give his scheduled dose of acetylsalicylic acid early, because it may help to dissolve the clot.

d. Check his capillary blood glucose with a point-of-care meter and report the value with the time.

Answer: d — Low glucose can mimic stroke and is quickly found and treated; a glucose check is recommended early in every suspected stroke (section 31.2, Clinical Safety: Check the Glucose). Option a is unsafe; he must stay NPO, including oral medications, until a validated swallowing screen is completed. Option b delays action; stroke treatment is time-critical. Option c is unsafe; antithrombotic medicine is never given until imaging rules out hemorrhage and the stroke team decides.

3. [CORE] Mr. Tran's glucose is 7.4 mmol/L. Which action by the RPN is most appropriate?

a. Activate the in-hospital code stroke or rapid response as policy directs and notify the RN at the same time.

b. Page the attending physician and wait at the nursing station for a return call before taking any further action.

c. Document the findings and plan to reassess him at 0400 with the next set of scheduled vital signs.

d. Call his daughter to ask whether he has ever had weakness like this before deciding whom to call.

Answer: a — Every nurse who finds new stroke signs acts at once and calls for help through the hospital's in-hospital code stroke or rapid response process, keeping the RN informed (section 31.2, The First Hour; Chapter 6). Option b leaves the patient and adds delay. Option c delays care for a time-critical emergency. Option d delays escalation; family information can be gathered while the team is on its way.

4. [CORE] Mr. Tran says, slowly and with slurred words, "I'm so thirsty. Can I have some juice?" Which response by the RPN is best?

a. "You can have a small sip of juice through a straw, which is safer for you than drinking from a cup."

b. "I know you're thirsty. You can't drink until your swallowing is checked. I'll moisten your mouth for you."

c. "Please try not to talk right now, because talking will make the weakness in your face and arm worse."

d. "The doctor will explain everything later, so try to rest and stop worrying about it until the doctor arrives."

Answer: b — The CSBPR keep people with suspected stroke NPO until a validated swallowing screen is done; the nurse explains this simply, acknowledges his thirst and offers mouth care as policy allows (section 31.2, The First Hour). Option a is unsafe because a straw does not make swallowing safe before screening. Option c is false and discourages communication. Option d dismisses his concern and gives no explanation.

5. [CORE] A patient asks why the team is rushing to treat her stroke. Which explanation by the nurse is most accurate?

a. "The whole area of your brain affected by the stroke died at the moment it began, so treatment now is only meant to prevent another stroke."

b. "The medicines work only if they are given within the first hour after the stroke, and after that they cannot help anyone."

c. "Around the most damaged area is brain tissue that has stopped working but can still recover if blood flow returns soon."

d. "Rushing treatment is mainly a hospital policy for keeping emergency department waiting times short for all patients."

Answer: c — The penumbra is tissue that has stopped working but can recover if blood flow returns before it becomes part of the core; "time is brain" (section 31.1, Why Time Matters). Option a is wrong; not all tissue dies at once. Option b is wrong; thrombolysis can be given within 4.5 hours of onset and clot removal up to 24 hours in selected patients. Option d misstates the reason for speed.

6. [CORE] A 59-year-old man reports that his right hand went numb and his speech was jumbled for 20 minutes yesterday, and that he now feels "back to normal." Which response by the nurse is best?

a. "Because your symptoms went away completely, this was most likely a pinched nerve and is not an emergency."

b. "If the same symptoms happen again and last more than 24 hours, then you should call 9-1-1 for an ambulance."

c. "Make an appointment with your family doctor within the next month to have your blood pressure and cholesterol checked."

d. "This sounds like a warning stroke. Stroke risk is highest in the next few days, so you need urgent assessment today."

Answer: d — Brief stroke-like symptoms that fully resolve suggest a TIA, a warning of stroke; risk is highest in the first 48 hours, and the CSBPR call for urgent assessment (section 31.1, Types of Stroke; section 31.5). Option a dismisses a TIA. Option b is unsafe; any new stroke sign calls for 9-1-1 at once, without waiting. Option c delays assessment far too long.

7. [CORE] The nurse teaches a community group about the FAST signs of stroke. Which statement by a participant shows a need for more teaching?

a. "If my husband's face suddenly droops on one side, I should call 9-1-1 even if his arms are fine."

b. "If my sister can't raise both of her arms, I should note the time and call 9-1-1 right away."

c. "If my father's speech is suddenly slurred or jumbled, that is one of the FAST signs of stroke I should act on."

d. "If I have stroke signs, I should drive myself to the nearest hospital because it is faster than waiting."

Answer: d — Heart & Stroke advises calling 9-1-1 and not driving to hospital, because an ambulance will take the person to the nearest hospital able to give urgent stroke care (section 31.2, Signs of Stroke). Options a, b and c are correct: one FAST sign is enough to act, and the time the signs began matters.

8. [CORE] Besides the FAST signs, which sudden signs can indicate a stroke? Select all that apply.

a. Blurred or double vision

b. A sudden, severe headache that usually comes with other signs

c. Numbness that mostly affects one side of the body

d. Trouble with balance

e. Gradual memory loss over several months

f. A dry cough that has lasted for two weeks

Answer: a, b, c, d — Heart & Stroke lists sudden vision changes, sudden severe headache, one-sided numbness and balance problems as less common signs of stroke (section 31.2, Signs of Stroke). Gradual memory loss (e) is not sudden and suggests another cause, such as dementia (Chapter 8). A two-week cough (f) is not a neurologic sign.

9. [CORE] A patient has an ischemic stroke in the right cerebral hemisphere. Which findings should the nurse expect?

a. Weakness of the left arm and leg and inattention to the left side of the body and space

b. Weakness of the right arm and leg and difficulty finding words and understanding speech

c. Weakness of both legs with normal arm strength and normal attention to both sides

d. Loss of hearing in the right ear with no weakness of the face, arms or legs

Answer: a — Each hemisphere controls the opposite side of the body, and neglect is more common after right hemisphere damage (section 31.2, Signs of Stroke). Option b describes a typical left hemisphere stroke. Option c does not fit a single hemisphere stroke. Option d is not a typical hemisphere stroke pattern.

10. [CORE] A 70-year-old man with type 2 diabetes who takes insulin is found confused, sweating, with slurred speech and weakness of the right arm. What should the nurse do first after calling for help?

a. Keep him NPO and wait for the CT scan, because a stroke is the most likely cause of his signs.

b. Ask him to drink a glass of orange juice right away, because the signs suggest low blood glucose.

c. Check his capillary blood glucose and treat a low value at once using the hypoglycemia protocol.

d. Give his scheduled insulin dose so that his glucose does not rise during the stroke assessment.

Answer: c — Hypoglycemia is a common stroke mimic that causes one-sided weakness and slurred speech; the glucose is checked early and a low value is treated at once by protocol, while stroke assessment continues (section 31.2, Stroke Mimics; section 22.4). Option a skips a quick, reversible cause. Option b is unsafe because his swallowing is uncertain; the protocol's non-oral route is used. Option d could worsen a low glucose.

11. [CORE] An RPN on a medical unit finds new facial droop and arm drift in a patient assigned to the RPN. The hospital's policy allows any nurse to activate the in-hospital code stroke. Which action reflects the RPN's role?

a. Ask the RN to come and confirm the findings before the RPN calls anyone, because only an RN may decide that a patient is unstable.

b. Wait until the RN has finished giving medications to another patient, then report the findings so that the RN can decide what to do.

c. Activate the code stroke as policy allows, stay with the patient and inform the RN, because every nurse acts at once on new stroke signs.

d. Transfer the patient's care to the RN and return to other assigned patients, because stroke care is outside the RPN's scope of practice.

Answer: c — Every nurse who notices deterioration acts at once and escalates; here the employer policy gives the RPN the authority to call the code stroke, and the RPN consults the RN as the patient's needs change (section 31.2, The First Hour; section 1.3). Options a and b delay time-critical care, and no CNO rule makes the RPN wait for an RN to escalate. Option d abandons the patient; the RPN continues to care for the patient within their competence while the team takes over.

12. [CORE] On a stroke unit, an RPN is caring for a patient who received tenecteplase 6 hours ago. The employer's policy states that patients in the first 24 hours after thrombolysis are assigned to an RN. What should the RPN do?

a. Continue the assignment, because CNO standards allow an RPN to care for any patient once 6 hours have passed since thrombolysis.

b. Discuss the assignment with the charge nurse, because the employer's policy sets this context in addition to the RPN's own competence.

c. Refuse to enter the room until the patient is 24 hours past treatment, because the RPN is not allowed to give any care to this patient.

d. Accept the assignment without comment, because an RPN's scope is defined only by the RPN's own competence and experience.

Answer: b — Using CNO's authority, competence and context, the RPN considers employer policy as part of the practice context and raises the mismatch with the charge nurse (section 1.3; section 31.3). Option a is wrong; CNO does not set time-based or patient-type rules for RPN assignments, and the employer policy applies. Option c is wrong; the RPN can still help and must act on any deterioration. Option d ignores context and employer policy.

13. [CORE] Thirty minutes into an alteplase infusion, a patient says, "I have a terrible headache," and vomits. The patient is now harder to rouse. What should the nurse do first?

a. Give the ordered antiemetic and an analgesic for the headache, then recheck the neurologic status in one hour.

b. Slow the infusion rate by half and recheck the patient's blood pressure in 15 minutes before calling anyone.

c. Raise the head of the bed and offer a few sips of water to help settle the patient's nausea.

d. Stop the infusion as the protocol directs and call the stroke physician at once for an urgent assessment.

Answer: d — A new headache, vomiting and a falling level of consciousness suggest intracranial hemorrhage; the infusion is stopped and the stroke physician called at once, with urgent CT to follow (section 31.3, Thrombolysis; Table 31.2). Option a treats symptoms and delays recognition of a bleed. Option b continues the thrombolytic and delays escalation. Option c gives fluid by mouth to a patient who may be unsafe to swallow and delays care.

14. [CORE] During an alteplase infusion, the nurse notices that the patient's upper lip and tongue are swelling. The patient takes ramipril, an ACE inhibitor, at home. Which action should the nurse take first?

a. Document the swelling and recheck it in 30 minutes, because mild swelling is expected during thrombolysis.

b. Stop the infusion if it is still running, call for help and assess the airway, preparing for airway support.

c. Give the patient a cold drink to reduce the swelling, because the cold will shrink the swollen tissue.

d. Tell the patient to stop taking ramipril after discharge, because it caused the swelling, and then continue the infusion.

Answer: b — Orolingual angioedema can threaten the airway; the CSBPR advise stopping the infusion at the first sign and treating it, and ACE inhibitor use is linked to higher risk (section 31.3, Thrombolysis). Option a delays care. Option c is unsafe; the patient is NPO and may not be able to swallow. Option d continues the trigger and leaves the airway risk untreated.

15. [CORE] Two hours after endovascular thrombectomy through the right femoral artery, the nurse finds a growing, firm swelling at the right groin site. What is the nurse's priority action?

a. Apply firm pressure above the site and call for help at once while checking the right leg's pulses and colour.

b. Help the patient walk to the bathroom so that the nurse can see whether the swelling gets worse with movement.

c. Apply a warm compress to the groin to improve blood flow and reduce the size of the swelling over the next hour.

d. Remove the dressing and wash the site with soap and water to check whether the swelling is caused by an infection.

Answer: a — A growing, firm lump at the access site suggests bleeding into the tissue; the nurse applies pressure, calls for help and checks circulation to the limb (section 31.3, Endovascular Thrombectomy; Table 31.2). Option b increases bleeding and is unsafe. Option c can increase bleeding. Option d delays treatment of a bleed and does not reflect the likely cause.

16. [CORE] Why is non-contrast CT of the head done first for a person with suspected acute stroke?

a. It shows the size of the penumbra exactly, so that the team knows how much brain can be saved.

b. It is used mainly to find out whether the person has had a stroke at some time in the past.

c. It shows whether there is bleeding in the brain, which changes treatment completely.

d. It replaces the need for a neurologic examination, so the team can skip that step to save time.

Answer: c — Non-contrast CT rules out hemorrhage, which decides whether clot-dissolving treatment can be considered; CTA then shows the blocked artery (section 31.2, The First Hour). Option a is wrong; perfusion imaging, not non-contrast CT, estimates tissue at risk. Option b is not its main purpose. Option d is wrong; the rapid neurologic examination is still done.

17. [CORE] A family member asks why their father is being moved to the stroke unit instead of staying on the general medical floor. Which reply by the nurse is most accurate?

a. "The stroke unit is mainly for patients who have had a hemorrhagic stroke; your father had a clot, so it is just where a bed was free."

b. "He will stay on the stroke unit only until his imaging is done, and then he will return to the medical floor for rehabilitation."

c. "On the stroke unit, a stroke-trained team works together, and people cared for there are more likely to survive and return home."

d. "Stroke units are used because they have more equipment for intensive care, such as a ventilator ready at every bed."

Answer: c — Organized stroke unit care by an interprofessional team lowers death and dependency, and patients are more likely to be alive, living at home and independent (section 31.3, The Stroke Unit). Option a is wrong; stroke units care for all stroke types. Option b misdescribes the unit's purpose. Option d confuses a stroke unit with an intensive care unit.

18. [RN] A 64-year-old woman with a large vessel occlusion is last known well 11 hours ago. Imaging shows a small core and a large area of penumbra, and the team plans thrombectomy. Her son asks how treatment can still help so late. Which explanation by the RN is most accurate?

a. "Her strong collateral vessels have kept the area at risk alive longer than usual, so restoring flow can still save that tissue."

b. "After 6 hours all of the tissue at risk has died, so the procedure now is only to prevent a second stroke in the same artery."

c. "Thrombectomy works at any time after a stroke, because the time since last known well no longer matters with modern treatment."

d. "The imaging shows that the stroke was caused by bleeding, which can be removed safely at any time after it starts."

Answer: a — Collateral circulation varies between people and can keep the penumbra viable for longer; selected patients with a small core and salvageable tissue can benefit from thrombectomy up to 24 hours from LKW (section 31.1, Why Time Matters; section 31.3, Endovascular Thrombectomy). Option b is wrong; imaging shows tissue still at risk. Option c is wrong; time still matters, and the window is limited. Option d is wrong; thrombectomy treats a blocked artery, not a hemorrhage.

19. [RN] Three hours after tenecteplase, a patient's blood pressure has risen from 168/90 to 204/110 mm Hg. She reports a new headache, and her NIHSS score has risen by 4 points. Which interpretation and action by the RN are best?

a. The headache is a common, harmless effect of tenecteplase, so the RN gives acetaminophen as ordered and rechecks in an hour.

b. These findings suggest a symptomatic intracranial hemorrhage, so the RN calls the stroke physician now and prepares for urgent CT.

c. The rise in NIHSS reflects normal fluctuation after stroke, so the RN continues neurologic checks at the scheduled interval.

d. The high blood pressure is the only problem, so the RN gives the ordered antihypertensive and waits for it to take effect.

Answer: b — The CSBPR name neurologic decline, a sudden rise in blood pressure and a new headache as signs of symptomatic intracranial hemorrhage after thrombolysis, calling for immediate assessment and non-contrast CT (section 31.3, Thrombolysis). Option a misses a bleed. Option c dismisses a 4-point rise. Option d treats one finding without recognizing the pattern; blood pressure is managed as ordered, but the physician is called at once.

20. [RN] A patient with an acute ischemic stroke is a candidate for thrombolysis. Her blood pressure is 196/112 mm Hg. Which statement reflects the CSBPR?

a. Thrombolysis can start now, because blood pressure is treated only if it rises above 220/120 mm Hg.

b. Blood pressure should be lowered quickly to below 120/80 mm Hg before treatment to prevent bleeding in the brain.

c. Blood pressure targets do not apply once thrombolysis has started, so the RN checks it only if the patient has symptoms.

d. Blood pressure should be lowered and kept below 185/110 mm Hg before and during treatment and for the next 24 hours.

Answer: d — For thrombolysis candidates, the CSBPR state that blood pressure is lowered and kept below 185/110 mm Hg as treatment starts, during it and for 24 hours (section 31.3, Thrombolysis). Option a confuses the threshold for patients who are not receiving reperfusion treatment. Option b is wrong; rapid or excessive lowering is avoided because the penumbra depends on blood pressure. Option c is wrong; close monitoring continues for 24 hours.

Case: Margaret Hill (Questions 21–26): Margaret Hill, 72, is on day 3 after a left hemisphere ischemic stroke with right-sided weakness and expressive aphasia. She failed the swallowing screen on admission. The SLP assessed her on day 2 and ordered a minced and moist diet with mildly thick fluids, upright positioning and supervision for all meals. At lunch, the nurse finds her daughter feeding her homemade chicken noodle soup with thin broth. Ms. Hill coughed several times. At 1900 the same day, her temperature is 38.3 °C, heart rate 104, respiratory rate 26, blood pressure 138/82 mm Hg and oxygen saturation 89% on room air, down from 95% that morning. Her voice sounds wet. Crackles are heard over the right lower lobe. Capillary glucose is 6.4 mmol/L. Her right-sided weakness is unchanged.

21. [CORE] Which findings at 1900 should the nurse recognize as cues that need follow-up? Select all that apply.

a. Temperature of 38.3 °C

b. Oxygen saturation of 89% on room air

c. Right-sided weakness that is unchanged from the morning

d. Crackles over the right lower lobe

e. Capillary glucose of 6.4 mmol/L

f. Wet-sounding voice and respiratory rate of 26

Answer: a, b, d, f — A temperature above 37.5 °C needs closer monitoring and a search for infection such as pneumonia (a; section 31.5). A fall in saturation from 95% to 89% shows worsening oxygenation (b). New crackles, a wet voice and a fast respiratory rate point to fluid or secretions in the lungs (d, f). Weakness that is unchanged is not a new neurologic cue (c). A glucose of 6.4 mmol/L is within a normal range and does not explain her findings (e).

22. [CORE] Which explanation best links Ms. Hill's findings?

a. The fever and crackles are signs of a urinary tract infection that has spread to the lungs through the bloodstream since admission.

b. Thin broth, which her swallowing plan did not allow, likely entered her airway and has led to aspiration pneumonia.

c. Her new stroke symptoms have extended to the brainstem, causing a fever and low saturation without lung involvement.

d. Her aphasia has made her anxious, and anxiety explains the rapid breathing, the fast heart rate and the wet-sounding voice.

Answer: b — She has dysphagia, was given thin fluids that her plan did not allow, coughed while eating, and now has fever, crackles, a wet voice and falling saturation, a pattern that suggests aspiration pneumonia (b; sections 31.5 and 13.2). Nothing suggests a urinary source (a). Her neurologic findings are unchanged, and crackles show lung involvement (c). Anxiety does not cause fever, crackles or low saturation (d).

23. [RN] Which hypothesis should the nurse treat as the priority at 1900?

a. Dehydration from limited fluid intake since admission, which needs an increase in thickened fluids offered by mouth tonight

b. Constipation from reduced mobility, which can cause fever in older adults and needs a bowel program started tonight

c. Aspiration pneumonia with hypoxemia, which can progress to respiratory failure and sepsis and needs escalation now

d. Post-stroke depression shown by refusing the hospital meals, which needs a validated screening tool used before discharge

Answer: c — Falling saturation, tachypnea, fever and crackles after likely aspiration threaten her airway and breathing, so aspiration pneumonia with hypoxemia is the priority (c; section 31.5; Chapters 4 and 6). Dehydration may need attention, but offering more fluids by mouth now is unsafe (a). Constipation does not explain her lung findings (b). Mood screening matters but is not urgent (d).

24. [CORE] What should the nurse do first?

a. Stop all oral intake, sit her upright, give oxygen per order or policy, and report to the RN and physician using SBAR.

b. Give acetaminophen by mouth with mildly thick fluids to lower the fever, and recheck her temperature in 1 hour.

c. Ask her daughter to bring a thicker soup tomorrow so that Ms. Hill can continue to eat the foods she likes.

d. Document the findings in her chart, increase vital signs to every 4 hours, and ask the night nurse to report any further change.

Answer: a — The nurse stops oral intake to prevent further aspiration, positions her upright, treats low saturation as ordered or per policy, and escalates at once with SBAR (a; section 31.5; Chapter 6). Giving medicine by mouth before her swallowing is reassessed adds risk (b). Changing the soup does not address her current deterioration (c). Waiting with less frequent checks delays care for a deteriorating patient (d).

25. [CORE] The physician orders a chest X-ray, antibiotics and NPO status. Which statement by the nurse to Ms. Hill's daughter is best?

a. "Your mother can have whatever she likes to eat as long as you stay with her and watch her closely while she eats."

b. "The soup caused this infection, so it is best that you do not visit at mealtimes for the rest of her stay in hospital."

c. "Thin liquids are the main problem, so any solid food from home is safe if you cut it into small pieces before feeding her."

d. "Her swallowing is not yet safe for thin liquids. The speech-language pathologist will reassess her, and we will show you how to help with meals."

Answer: d — The nurse explains the reason for the plan without blame, refers her to the SLP for reassessment and involves the daughter in supervised mealtime teaching (d; sections 31.5 and 24.3). Supervision alone does not make unsafe textures safe (a). Blaming the family and excluding them works against the CSBPR's call to include families as team members (b). Food from home must match the texture the SLP sets, so small pieces of any food are not automatically safe (c).

26. [CORE] Two days later, which finding best shows that Ms. Hill's care is working?

a. She asks for regular-textured toast and coffee with breakfast and says that she is hungry this morning.

b. Her temperature is 37.0 °C, her oxygen saturation is 95% on room air, and her chest is clear on auscultation.

c. Her daughter has brought a small blender so that she can prepare soups and other soft meals at home after discharge.

d. Her heart rate is 112, her respiratory rate is 24, and she is coughing up thick yellow sputum after meals.

Answer: b — A normal temperature, saturation back to her baseline and a clear chest show that the pneumonia is resolving (b; section 31.5). Asking for regular food shows appetite, not safe swallowing, and diet changes come from the SLP (a). A blender may help later, but it does not show her condition improving (c). Ongoing tachycardia, tachypnea and sputum after meals suggest that the problem persists (d).

27. [CORE] A patient with an intracerebral hemorrhage had a Glasgow Coma Scale score of 14 at 0800. At 1000 the score is 11, and the patient vomits and reports a worse headache. What should the nurse do?

a. Recheck the score in 1 hour, because a change of three points is expected in the first 24 hours after a hemorrhage.

b. Give the as-needed antiemetic and analgesic and document that the headache improved after treatment.

c. Call for urgent help now, keep the airway clear, and report the decline in score with the new signs using SBAR.

d. Lower the head of the bed flat to improve blood flow to the brain and wait for the physician's morning rounds.

Answer: c — A falling GCS score with vomiting and a worse headache suggests that the bleed or swelling is growing and ICP is rising, so the nurse escalates at once and protects the airway (c; sections 31.4 and 30.4; Chapter 6). A three-point drop is never an expected change (a). Treating symptoms and documenting hides a dangerous decline (b). Lying flat can worsen ICP, and waiting delays care (d).

28. [CORE] A 52-year-old man arrives at the emergency department. Which statement most strongly suggests subarachnoid hemorrhage?

a. "I have had a dull headache on and off for the past week, worse in the evening after a long day at work."

b. "My headache came on suddenly while I was lifting boxes. It is the worst headache of my life."

c. "I get headaches with flashing lights before them, usually about once a month, and today's feels the same."

d. "My headache started after I bumped my head on a cupboard door this morning, and now there is a small lump."

Answer: b — A headache that starts suddenly and is described as the worst of the person's life is the classic presentation of aneurysmal SAH (b; section 31.4). A recurring dull headache (a) and a familiar migraine pattern with aura (c) do not fit SAH. A minor bump with a lump suggests a local injury, which is assessed under head injury (d; Chapter 32).

29. [CORE] A patient admitted 30 minutes ago with an ischemic stroke asks for water to take her usual morning tablets. The swallowing screen has not been done. What should the nurse do?

a. Explain that nothing can be taken by mouth until her swallowing is screened, and arrange the screen and mouth care.

b. Give the tablets with a small sip of water while watching her closely for coughing, choking or a wet-sounding voice afterward.

c. Crush the tablets into applesauce, since puréed food is safe for people with dysphagia after a stroke.

d. Hold the tablets until discharge and record them as refused, because the stroke team will review them later.

Answer: a — The CSBPR states that a trained professional screens swallowing with a valid tool before any oral intake, including medications (a; section 31.5). A patient may aspirate silently, so watching for coughing is not safe (b). Puréed food is not automatically safe, and some tablets must not be crushed (c). Essential medicines are not simply withheld; the nurse reports the need for another route (d).

30. [CORE] A patient had an ischemic stroke 10 hours ago. A family member asks why the patient is not being walked in the hallway right away. What is the best response?

a. "Patients are kept on bed rest for a full week after a stroke so that the brain can heal before any movement."

b. "Patients are walked as far as possible within the first few hours, because the sooner they walk, the better."

c. "Guidelines advise against intense activity in the first 24 hours. The team will get your relative up once stable."

d. "Your relative will not walk until the rehabilitation unit, because nurses on the stroke unit do not mobilize patients."

Answer: c — The CSBPR advises against very early, high-intensity mobilization in the first 24 hours and starts mobilization once the patient is stable, ideally 24 to 48 hours after the stroke, with caution (c; section 31.5). A week of bed rest leads to complications (a). Intense walking in the first hours is the practice the CSBPR advises against (b). Nurses mobilize patients on the stroke unit with the team (d).

31. [CORE] A patient has a flaccid left arm after a stroke. Which actions protect the hemiplegic shoulder? Select all that apply.

a. Support the arm on a pillow or lap tray when the patient is sitting.

b. Help the patient move up in bed by pulling on both arms.

c. Teach the family to support the arm during transfers.

d. Set up an overhead pulley to keep the shoulder moving.

e. Avoid passive movement above 90 degrees unless the shoulder is positioned for it.

f. Keep the arm in a sling at all times, including after tone returns.

Answer: a, c, e — The CSBPR recommends supporting the arm at rest, teaching staff and family to handle it, protecting it during transfers and limiting passive movement above 90 degrees (a, c, e; section 31.5). Pulling on the weak arm (b) and overhead pulleys (d) can injure the shoulder. Slings are used only in the flaccid stage when no other support is possible and are discouraged afterward (f).

32. [CORE] A patient with expressive aphasia is trying to tell the nurse something. Which approach is best?

a. Speak loudly and slowly, because people with aphasia usually also have a hearing loss.

b. Finish each of the patient's sentences quickly so that the patient does not become frustrated.

c. Ask the family to answer for the patient so that the conversation is quicker and more accurate.

d. Reduce noise, ask short yes or no questions, offer a picture board, and give the patient time.

Answer: d — A quiet setting, short yes or no questions, visual supports and extra time help the person communicate (d; section 31.5). Aphasia is a language disorder, not a hearing problem (a). Finishing sentences for the patient can guess wrong and takes away the patient's voice (b). The patient remains the person the nurse speaks with; family can support but should not replace the patient (c).

33. [CORE] A patient with left unilateral neglect after a right hemisphere stroke is eating lunch. Which observation should the nurse expect?

a. Food eaten only from the right side of the tray

b. Inability to understand spoken instructions

c. Slurred speech with normal language content

d. Loss of sensation on the right side of the face

Answer: a — In left neglect, the person fails to notice the left side of space, so food on the left side of the tray is often left uneaten (a; section 31.5). Trouble understanding speech is receptive aphasia, which usually follows a left hemisphere stroke (b). Slurred speech with intact language is dysarthria (c). A right hemisphere stroke affects sensation on the left side of the body, not the right (d).

34. [CORE] Which statement about post-stroke depression reflects the CSBPR?

a. Screening is needed only after severe strokes, because mild strokes rarely affect mood in the first year.

b. Screening is done once, at admission, because the timing of post-stroke depression is well established in the research.

c. All people with stroke are screened if medically appropriate, by trained professionals using a validated tool.

d. Families are not screened or supported, because depression affects only the person who had the stroke.

Answer: c — The CSBPR states that all people with stroke should be screened for depression if medically appropriate, by trained professionals with a validated tool, especially at transition points (c; section 31.5). Depression can follow a mild stroke too (a). Repeated screening may be needed because the ideal timing is unclear (b). Family caregivers are also at risk of depression and need support (d).

35. [CORE] A patient says, "My arm went numb and weak for 20 minutes yesterday afternoon, but it is fine now." Based on the CSBPR, what should the nurse advise?

a. Book a routine appointment with your family doctor in the next few weeks, since the symptoms have gone away completely by themselves.

b. Take an ASA tablet at home and call 9-1-1 only if the numbness and weakness come back again later this week.

c. Go to an emergency department that provides stroke care immediately, because the risk of another stroke is highest now.

d. Rest for a few days and keep a diary of the symptoms to bring to the stroke prevention clinic next month.

Answer: c — The CSBPR states that people seen within 48 hours of new stroke or TIA symptoms are at the highest risk and should go at once to an emergency department able to provide stroke care (c; section 31.5). A routine visit (a) or a diary for next month (d) delays urgent assessment. Taking ASA before imaging is not the nurse's advice, and waiting for symptoms to return is unsafe (b).

36. [CORE] A patient who had a stroke 2 weeks ago is going home and asks, "When can I drive again?" What should the nurse explain?

a. "You may drive as soon as you feel confident, because the rules about driving apply only to commercial drivers."

b. "You can drive short distances right away if someone sits beside you to help watch the road."

c. "You can never drive again after a stroke, so we will help you sell your car before you go home."

d. "The guidelines advise not driving for a minimum of one month, and your team will check whether you are fit to drive."

Answer: d — The CSBPR advises not driving for a minimum of one month after a stroke and calls for assessment of fitness to drive, with provincial or territorial law governing licensing (d; section 31.6). Confidence alone does not show fitness, and the advice is not limited to commercial drivers (a). A passenger cannot make up for deficits such as neglect (b). Many people return to driving after assessment (c).

37. [CORE] An RPN on a stroke unit has not completed the employer's dysphagia screening training. A newly admitted patient is NPO and asks for a drink. What should the RPN do?

a. Use a screening tool the RPN learned in school, because any swallowing screen is acceptable on a stroke unit.

b. Keep the patient NPO, give mouth care, and ask a nurse trained in the employer's screening tool to complete the screen.

c. Give the patient a few ice chips, because ice chips do not count as oral intake during the stroke workup.

d. Tell the patient that only a physician may decide when a person with a stroke can drink, so the wait may be quite long tonight.

Answer: b — Screening is done by a trained professional with a valid tool that the employer authorizes, so a nurse without that training lacks competence and authority in this context (b; sections 31.5 and 1.3). Not every tool or method is acceptable (a). Ice chips are oral intake and can be aspirated (c). Trained nurses can screen when policy allows; it is not only a physician's decision (d).

38. [CORE] An RPN is caring for a patient on day 4 after an ischemic stroke. The patient suddenly cannot lift the left arm, which was strong an hour ago. What should the RPN do first?

a. Note the time the patient was last known well, check the glucose, and call for help at once per the in-hospital stroke policy, informing the RN.

b. Document the weakness and reassess at the next scheduled neurologic check in 4 hours, since some change is expected.

c. Wait for the RN to finish a medication pass before mentioning the change, because RPNs do not escalate neurologic changes.

d. Help the patient to the chair and encourage exercise of the arm to see whether the strength returns by itself with movement.

Answer: a — Every nurse who notices new stroke signs acts at once: noting the last known well time, checking glucose and activating help per policy, with the RN informed (a; section 31.2; Scope in Practice box, section 31.6). New weakness is not an expected change (b). RPNs escalate deterioration without delay (c). Moving the patient delays assessment and adds fall risk (d).

39. [RN] A patient with an acute intracerebral hemorrhage has a blood pressure of 188/96 mm Hg. Which statement reflects the CSBPR on blood pressure in acute ICH?

a. Blood pressure is not treated in the first 48 hours, because lowering it always reduces blood flow to the brain.

b. Systolic pressure is lowered to below 100 mm Hg within the first hour to stop the bleeding as fast as possible.

c. Blood pressure is checked every 4 hours, and treatment starts only if systolic pressure stays above 220 mm Hg for a day.

d. Lowering systolic pressure to below 140 mm Hg does not worsen neurologic outcomes, and blood pressure is checked every 15 minutes at first.

Answer: d — The CSBPR states that lowering systolic pressure to a target below 140 mm Hg does not worsen neurologic outcomes, that checks begin on arrival and every 15 minutes after that, and that an individual target below 140 to 160 mm Hg for 24 to 48 hours may be reasonable (d; section 31.4). Leaving high pressure untreated (a) and checking only every 4 hours with a very high threshold (c) do not match the CSBPR. A systolic pressure below 100 mm Hg is not a target and risks poor brain perfusion (b).

40. [RN] On day 7 after coiling of a ruptured aneurysm, a patient who had been alert becomes drowsy and confused and has new weakness of the right arm. The serum sodium is 129 mmol/L. Which interpretation and action are best?

a. These are expected effects of the anesthetic used during the coiling; the nurse reassesses at the next routine neurologic check.

b. These suggest delayed cerebral ischemia, possibly worsened by low sodium and volume loss; the nurse escalates immediately.

c. These suggest the aneurysm is still bleeding; the nurse restricts all fluids to 1 L per day to correct the sodium level.

d. These suggest a migraine; the nurse dims the lights, gives an as-needed analgesic and reassesses in 2 hours.

Answer: b — New neurologic decline days after aneurysmal SAH suggests delayed cerebral ischemia, and low sodium with volume loss can contribute, so the nurse reports at once (b; section 31.4). Anesthetic effects do not appear on day 7 (a). The aneurysm has been secured, and restricting fluid can worsen the low blood volume that sodium loss through the kidneys causes, which is linked to DCI (c; sections 31.4 and 3.4). A migraine does not explain new focal weakness and confusion (d).

32 Traumatic Brain and Spinal Cord Injury and Chronic Neurologic Disorders

LEARNING OUTCOMES & COMPETENCY MAPPING

By the end of this chapter, you will be able to:

1. Recognize concussion and traumatic brain injury, including hematomas in older adults on anticoagulants, and prevent secondary brain injury.
2. Provide early and ongoing care for adults with spinal cord injury, including spinal motion restriction, breathing, bladder, bowel and skin.
3. Recognize autonomic dysreflexia as an emergency and take the first actions in order.
4. Support adults living with multiple sclerosis and Parkinson disease, including giving Parkinson medications on time in hospital.
5. Recognize respiratory decline in myasthenia gravis and Guillain–Barré syndrome and escalate early, using the CJMM.
6. Support adults and families living with ALS and other progressive neurologic diseases, including advance care planning.
7. Distinguish RN and RPN roles in neurologic injury and chronic neurologic care using CNO's authority, competence and context.

How the outcomes map to the CNO entry-to-practice competencies

Outcome	RN competency role (CNO, 2019a)	RPN competency category (CNO, 2019b)
1, 2, 3, 4, 5	Clinician; Scholar	Foundations of Practice
4, 6	Educator; Advocate	Foundations of Practice; Ethical Practice
7	Professional; Coordinator	Legal Practice; Collaborative Practice

Introduction

An injury to the brain or spinal cord can happen in a second: a slip on an icy step, a crash on the highway, a hard check into the boards. Other neurologic diseases unfold over months or years. Both kinds of illness can change how a person moves, thinks, breathes and lives, and both ask nurses to notice small changes early. A patient who is a little drowsier after a head injury, a sudden rise in blood pressure in a person with a high spinal cord injury, or a weaker cough in a person with a neuromuscular disease can each be the first sign of a threat to life.

This chapter is the book's home for traumatic and chronic neurologic conditions in adults. Section 32.1 covers traumatic brain injury, from concussion to bleeding around the brain, with attention to older adults who fall while taking anticoagulants (blood thinners). Section 32.2 covers spinal cord injury: early care, breathing, autonomic dysreflexia and life after injury. The second half of the chapter turns to chronic and progressive disorders: multiple sclerosis (32.3), Parkinson disease (32.4), myasthenia gravis and Guillain–Barré syndrome (32.5), and amyotrophic lateral sclerosis and living with progressive neurologic disease (32.6).

The chapter builds on earlier ones. Scope of practice for registered nurses (RNs) and registered practical nurses (RPNs) is taught in section 1.3, and the Clinical Judgment Measurement Model (CJMM) in section 1.4. In other provinces and territories, practical nurses (PNs) are often called licensed practical nurses (LPNs); this chapter uses "the nurse" unless the roles differ. Neurologic assessment and the Glasgow Coma Scale (GCS) are in section 30.2, increased intracranial pressure (ICP) in section 30.4 and seizures in section 30.5. Recognizing deterioration, shock and rapid response are in Chapter 6, airway and ventilation in Chapter 15, anticoagulant reversal in Chapter 19, and fractures and spinal surgery in Chapter 33. Disability and accessibility are in Chapter 2.

32.1 Traumatic Brain Injury and Concussion

How Brain Injury Happens

A **traumatic brain injury (TBI)** is damage to the brain from an outside force, such as a blow to the head or a jolt that moves the brain quickly inside the skull (Ng & Lee, 2019; Poblete & Shaw, 2024). TBI is a major cause of injury in Canada. The Public Health Agency of Canada (PHAC) reports that more than 20,000 people are hospitalized for TBI each year (PHAC, 2020). From 2006/07 to 2017/18 there were 399,376 hospitalizations for head injuries in Canada, 63% of them among males, and falls were the leading cause. Rates of head injury hospitalization peaked among seniors over 85, at 897 per 100,000 males and 750 per 100,000 females (PHAC, 2020).

The cause of injury changes with age. In the PHAC (2020) report, falls were among the leading causes of TBI hospitalization for infants and for seniors aged 65 and older, sports and recreation for young teens aged 10 to 14, transportation for older teens and for adults of all ages, and assault for older teens and young adults aged 20 to 29. From 2002 to 2016, 22.6% of injury deaths in Canada involved a TBI, and TBI death rates rose sharply from age 65 (PHAC, 2020). These patterns point to prevention: fall prevention for older adults (Chapter 8), safe driving and helmets for younger adults.

Brain damage after trauma happens in two stages. **Primary brain injury** occurs at the moment of impact or sudden acceleration and deceleration (Poblete & Shaw, 2024). It may be **focal**, such as a bruise or a collection of blood in one area, or **diffuse**, spread through the brain when shearing forces stretch nerve fibres (Ng & Lee, 2019). Nurses cannot undo primary injury. **Secondary brain injury** is further damage in the hours and days that follow, from low oxygen, poor blood flow, swelling and harmful chemical changes in injured cells (Ng & Lee, 2019; Poblete & Shaw, 2024). Much of the nursing care in this section aims to prevent it.

Severity is often described with the GCS score after resuscitation: mild TBI is a score of 13 to 15, moderate 9 to 12, and severe 3 to 8 (Poblete & Shaw, 2024). The GCS itself is taught in section 30.2. Table 32.1 compares the main types of TBI.

Table 32.1 Types of traumatic brain injury: causes, signs and nursing focus (Government of British Columbia, 2024; Ng & Lee, 2019; Poblete & Shaw, 2024; Sundblom et al., 2022; Ottawa Hospital Research Institute, n.d.-a)

Injury	Typical cause	Key signs	Urgent nursing focus
Concussion (mild TBI)	A blow or jolt that moves the brain inside the skull, such as a fall, sports contact or collision	Headache, dizziness, blurred vision, fatigue, slowed thinking; brief loss of consciousness may or may not occur; standard imaging is normal	Check for red flags; give written and verbal teaching; plan follow-up and a gradual return to activity
Epidural hematoma	Impact to the head that causes bleeding between the skull and the dura	May lose consciousness briefly, wake and seem well, then become drowsy as the clot grows	Frequent neurologic checks even when the patient seems well; report any decline at once; prepare for urgent surgery
Acute subdural hematoma	Impact or rapid acceleration and deceleration that causes bleeding between the dura and the brain	A falling level of consciousness soon after injury; unequal or non-reacting pupils as pressure rises	Report decline at once; support oxygen and blood pressure; ask about anticoagulant or antiplatelet use
Chronic subdural hematoma	Often a low-energy fall in an older adult, sometimes weeks earlier or not remembered at all	New confusion or memory loss, headache, weakness, falls; may be mistaken for dementia	Treat new confusion as a possible brain injury; report; ask about falls and medications
Contusion	Impact that bruises brain tissue	Signs depend on the area injured; may worsen as swelling develops	Serial neurologic checks; prevent secondary injury
Diffuse axonal injury	Rapid acceleration and deceleration of the brain, without the need for a direct blow, that stretches and tears nerve fibres	Altered consciousness from the moment of injury; severity varies	Serial neurologic checks; prevent secondary injury; support the family

Concussion and Mild TBI

A **concussion** is a form of mild TBI in which a force, applied to the head or elsewhere on the body, makes the brain move rapidly inside the skull. The person may or may not black out briefly. Neurologic changes begin right away or within about 72 hours and usually settle on their own, and standard brain imaging, if done, shows nothing abnormal (Government of British Columbia, 2024). Concussion is a clinical diagnosis: the nurse and the clinician look for an injury that could reasonably have caused it, along with new signs, or symptoms that the examination supports (Government of British Columbia, 2024). Common symptoms include headache, dizziness, blurred vision, fatigue, trouble thinking, poor sleep and changes in mood (Government of British Columbia, 2024; Ottawa Hospital Research Institute, n.d.-b). In older adults, loss of consciousness is less common and GCS scores tend to be higher, so a concussion is easier to miss (Government of British Columbia, 2024).

Recognizing concussion. The Living Concussion Guidelines, the current Canadian guideline for adults, recommend that a suspected concussion be recognized as early as possible and that the person see a physician or nurse practitioner (NP), who confirms the diagnosis (Ottawa Hospital Research Institute, n.d.-a). The nurse asks how the injury happened, what the person remembers and how symptoms have changed since. Some findings point to a more serious injury and call for emergency care, including repeated vomiting (more than twice), a severe or worsening headache, increasing drowsiness, a seizure, new weakness or clumsiness, slurred speech, and ongoing fluid or blood from the ear or nose (*Brain Injury Advice Card*, n.d.). In the emergency department, the guideline lists factors that may justify keeping a person under observation, such as a GCS that stays abnormal, new focal neurologic signs, vomiting or severe headache, a bleeding disorder or anticoagulant use, ongoing intoxication, injuries to other body systems and age over 65 (Ottawa Hospital Research Institute, n.d.-a).

Deciding on a CT scan. Most people with concussion do not need imaging. The **Canadian CT Head Rule** (Stiell et al., 2001) is a clinical decision rule for people with a minor head injury. The BC guideline describes it as a way to rule out brain injuries that need neurosurgery without computed tomography (CT) in people older than 16 with a GCS of 13 to 15 (Government of British Columbia, 2024). The Living Concussion Guidelines recommend using it to decide on imaging in the first 24 to 48 hours, and note that it does not apply to people taking anticoagulants, who need extra consideration; plain skull x-rays are not recommended (Ottawa Hospital Research Institute, n.d.-a). The physician or NP applies the rule; the nurse makes sure that the history, including medications, reaches that clinician.

Rest and a graded return. Rest is brief. After a period of relative rest of about 24 to 48 hours, the guideline encourages a gradual return to daily activities, work and school, staying below the level of activity that clearly worsens symptoms (Ottawa Hospital Research Institute, n.d.-b, n.d.-c). Complete bed rest for more than three days should be avoided, and activities with a high risk of another concussion should be avoided, particularly in the first 7 to 10 days (Ottawa Hospital Research Institute, n.d.-c). A brief rise in symptoms with more activity is common. If symptoms worsen a lot or stay worse for more than about 24 hours, the person slows the pace (Ottawa Hospital Research Institute, n.d.-c). The BC guideline adds that the first 24 to 48 hours are a time of relative physical and mental rest, with little screen time and no driving; gentle activity, for example an easy walk, is fine if any rise in symptoms is small and passes quickly; and progress through its return-to-activity steps is no faster than one step per day (Government of British Columbia, 2024). Return to some form of work is encouraged when it does not risk another injury, with accommodations if needed. A person who still has symptoms should not drive (Ottawa Hospital Research Institute, n.d.-b, n.d.-c).

Persistent symptoms. Most adults are fully recovered and back to their usual activities within about a month (Ottawa Hospital Research Institute, n.d.-b). The BC guideline defines persisting symptoms as those lasting more than four weeks and states that at least one in six adults has them (Government of British Columbia, 2024). The Living Concussion Guidelines recommend follow-up with a primary care provider within one to two weeks, routine monitoring for depression and anxiety, and considering referral to interdisciplinary concussion services when symptoms last more than one month (Ottawa Hospital Research Institute, n.d.-b). The nurse teaches the person and a support person in writing and aloud, as the guideline recommends (Ottawa Hospital Research Institute, n.d.-a).

PATIENT EDUCATION

After a Concussion

Teach aloud and in writing, to the patient and a support person (Ottawa Hospital Research Institute, n.d.-a):

- **Go to the emergency department or call 9-1-1 for warning signs:** fainting, being very drowsy or impossible to wake; a constant severe headache, or one that is getting worse; throwing up more than twice; new confusion or trouble remembering new events; acting strangely or speech that makes no sense; a seizure; weakness, clumsiness or being unable to move part of the body; slurred speech or blurred vision; unsteadiness or loss of balance; or fluid or blood that keeps coming from the ear or nose (*Brain Injury Advice Card*, n.d.).
- **Rest briefly, then build up.** Take it easy for a day or two, then return to activities gradually. If symptoms stay worse for more than a day, slow down (Ottawa Hospital Research Institute, n.d.-c).
- **Avoid another head injury.** Stay out of contact sports and risky activities until a physician or NP says it is safe (Ottawa Hospital Research Institute, n.d.-c).
- **Do not drive** until symptoms have settled enough to drive safely (Ottawa Hospital Research Institute, n.d.-b).
- **Avoid alcohol, recreational drugs and sleeping pills** for at least the first 48 hours; they can make you feel worse and make it harder for others to tell whether the injury is affecting you (*Brain Injury Advice Card*, n.d.).
- **Expect recovery.** Most adults recover within about a month. See your primary care provider within one to two weeks (Ottawa Hospital Research Institute, n.d.-b).

Moderate and Severe TBI

Epidural hematoma. An **epidural hematoma** is a collection of blood between the skull and the dura, the tough outer covering of the brain. Some people lose consciousness briefly, wake up and seem well, then deteriorate as the clot grows. This period of seeming wellness is called the **lucid interval** (Ganz, 2013). A patient who is talking and joking can therefore still be in danger, and neurologic checks continue on schedule. A large clot is an indication for urgent surgery (Poblete & Shaw, 2024).

Subdural hematoma. A **subdural hematoma** is a collection of blood between the dura and the surface of the brain. An acute subdural hematoma appears soon after the injury and often causes a falling level of consciousness; a large one is removed surgically (Poblete & Shaw, 2024). A **chronic subdural hematoma** develops more slowly, often in older adults, when small veins that bridge from the brain surface to the dura tear after minor trauma and the collection keeps bleeding and growing (Sundblom et al., 2022). In one series of surgically treated patients, the mean age was nearly 80, falls on level ground were the most common cause, about half took an anticoagulant or antiplatelet medicine, the injury came from 72 hours to two months before diagnosis, and almost one-third had no known injury at all (Sundblom et al., 2022). Cognitive impairment was the main symptom in older adults and can be mistaken for dementia. Drainage through a small hole drilled in the skull (burr-hole drainage) improved neurologic function in most patients (Sundblom et al., 2022). Anticoagulant and antiplatelet medicines are a common cause of bleeding problems after TBI (Poblete & Shaw, 2024); reversal is covered in Chapter 19.

Contusion and diffuse axonal injury. A **contusion** is a bruise of brain tissue. **Diffuse axonal injury** is widespread stretching and tearing of nerve fibres caused by rapid acceleration and deceleration rather than a direct blow (Ng & Lee, 2019). Like other primary injuries, it typically alters consciousness from the moment of injury (Poblete & Shaw, 2024).

Preventing secondary injury. The injured brain is very sensitive to low oxygen and low blood pressure. The Emergency Neurological Life Support (ENLS) protocol for TBI from the Neurocritical Care Society recommends keeping oxygen saturation by pulse oximetry (SpO_2) at 94% or higher; keeping systolic blood pressure at or above 110 mm Hg for adults aged 15 to 49 or over 70, and at or above 100 mm Hg for those aged 50 to 69; raising the head of the bed to 30 degrees when ICP may be raised; keeping body temperature normal and preventing fever; and avoiding routine (prophylactic) hyperventilation, which is reserved for signs of brain herniation (Poblete & Shaw, 2024). The team may also consider a seizure-prevention medicine for the first seven days (Poblete & Shaw, 2024; section 30.5). The nurse also keeps values such as glucose and sodium within the targets the team sets. Managing raised ICP is taught in section 30.4.

Neurologic checks and escalation. The nurse performs neurologic checks, including GCS, pupils and limb strength, at the frequency ordered (section 30.2) and compares each result with the last. Using the CJMM (section 1.4), the nurse *recognizes cues* such as new drowsiness, a new headache, vomiting or a pupil change, *analyzes* them as possible bleeding or swelling, and *takes action* by reporting at once and calling the rapid response team if criteria are met (Chapter 6).

Agitation and post-traumatic amnesia. As people recover from moderate or severe TBI, many pass through **post-traumatic amnesia (PTA)**, a stage when awareness is poor and fluctuates, the person is disoriented, and new events are not reliably remembered. Its length helps predict outcome. The Canadian clinical practice guideline for rehabilitation after moderate to severe

TBI recommends assessing PTA repeatedly with a validated tool until it resolves, and keeping the person in a secure, supervised setting with low stimulation, consistent staff and orienting cues (KITE Research Institute, 2023). Restraints and sedating medicines are kept to a minimum, because antipsychotics and benzodiazepines may slow recovery and delay the person's emergence from PTA (KITE Research Institute, 2023). Agitation in PTA can look like delirium, which is covered in Chapter 8.

Supporting the family. Family members can play a useful role early in care (KITE Research Institute, 2023). The nurse explains what PTA and agitation mean, helps families keep visits short and calm when the person is easily overwhelmed, and includes them in planning for rehabilitation.

LIFESPAN CONSIDERATIONS

Head Injury in Older Adults

In older adults, falls cause more concussions than any other mechanism, and medicines such as sedatives, psychotropics and antithrombotics can increase the risk of injury (Government of British Columbia, 2024). In Canada, rates of hospitalization for head injury peak among people over 85 (PHAC, 2020).

- **Anticoagulants change the decision.** The Canadian CT Head Rule does not apply to people taking anticoagulants, and the Living Concussion Guidelines call for extra consideration of these patients; age over 65 and a bleeding disorder are among the factors that may justify observation (Ottawa Hospital Research Institute, n.d.-a). An older adult who hits their head while taking an anticoagulant is assessed promptly by a physician or NP, even if they seem well. Reversal of anticoagulants is in Chapter 19.
- **Signs can be subtle.** Older adults lose consciousness less often and may have a near-normal GCS after a concussion (Government of British Columbia, 2024).
- **Late bleeding.** A chronic subdural hematoma can appear days to weeks after a minor fall, or with no fall remembered, as new confusion, memory loss, weakness or more falls (Sundblom et al., 2022). The nurse does not assume that new confusion is dementia or delirium alone (Chapter 8) and reports it.

32.2 Spinal Cord Injury

Types and Levels of Injury

A **spinal cord injury (SCI)** is damage to the spinal cord that interrupts messages between the brain and the body below the injury, affecting movement, sensation and automatic functions such as blood pressure, bladder and bowel control. A **traumatic SCI** results from an outside force, such as a fall or a collision. A **non-traumatic SCI** results from disease; in Canada's national SCI registry, the most common cause of non-traumatic SCI was degenerative disease, followed by tumours (malignant, then benign), inflammation, vascular disorders, congenital or genetic disorders and infection (Praxis Spinal Cord Institute, 2024; Figure 32.1).

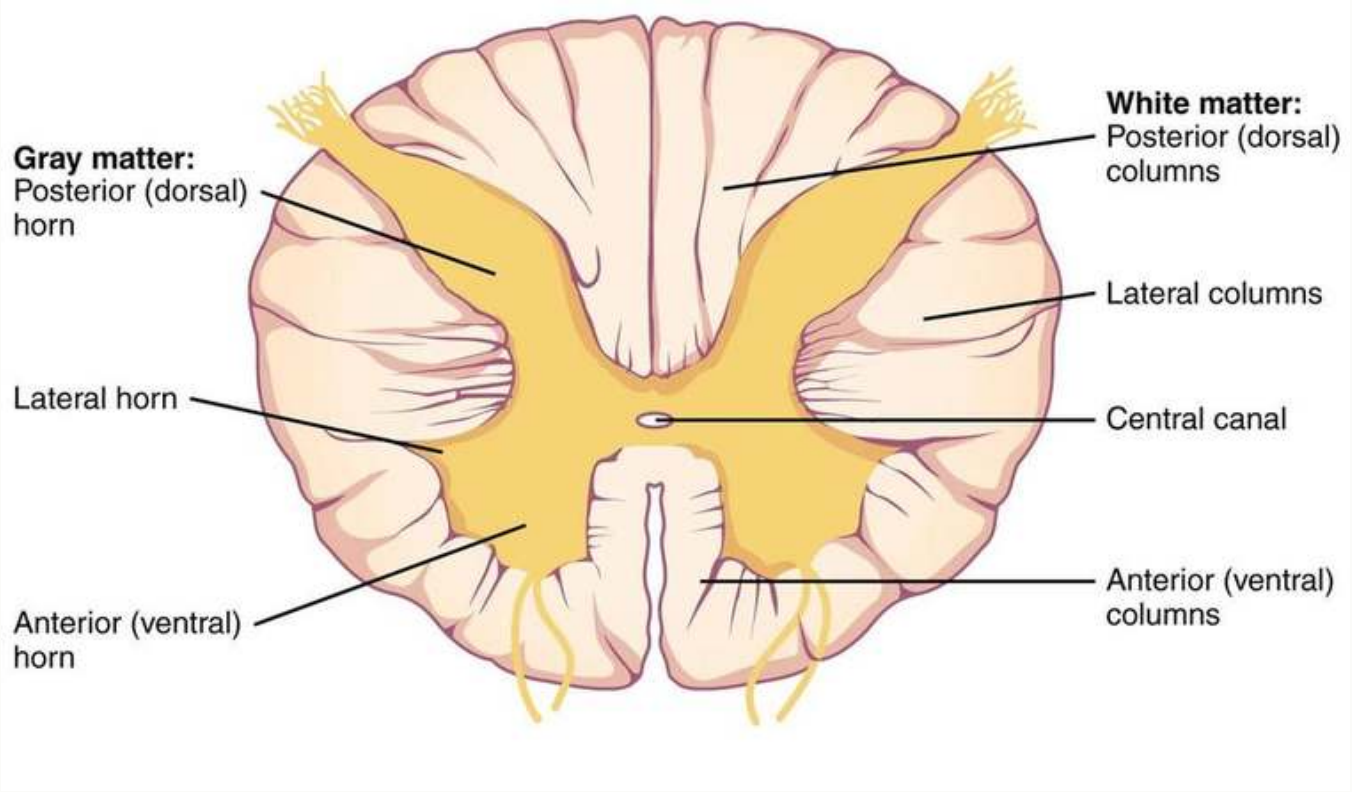

Figure 32.1 Cross-section of the thoracic spinal cord showing the sensory (posterior), autonomic (lateral) and motor (anterior) grey-matter horns and the surrounding white-matter tracts (cropped to the anatomical diagram panel). (credit: modification of "Figure 13.14, Cross-section of Spinal Cord" by J. Gordon Betts et al./OpenStax, Anatomy and Physiology 2e, CC BY-NC-SA 4.0)

Praxis Spinal Cord Institute (2024) estimates that about 86,000 people in Canada live with SCI, about 30,000 of them after a traumatic injury, and that about 1,100 people are discharged from hospital with a new traumatic SCI each year. Among registry participants in 2022, falls were the most common cause of traumatic SCI, followed by transportation, sports, other causes (such as work-related injuries) and assault. The average age at injury was 55 years for participants with traumatic SCI and 62 for those with non-traumatic SCI, and 76% of participants with traumatic SCI were male (Praxis Spinal Cord Institute, 2024).

Level. The **neurologic level of injury** is the lowest segment of the spinal cord with normal sensation and antigravity muscle strength on both sides, with all function above it intact (Snider et al., n.d.). An injury to the cervical (neck) cord causes **tetraplegia**: weakness or paralysis that affects the arms, trunk and legs. An injury to the thoracic, lumbar or sacral cord causes **paraplegia**, which spares the arms but affects the trunk, legs or both, depending on the level. Among people with traumatic SCI in the registry, tetraplegia was more common than paraplegia (Praxis Spinal Cord Institute, 2024; Figure 32.2).

Completeness. An injury is **complete** when no sensation or movement is preserved in the lowest sacral segments (S4–S5), around the anus. It is **incomplete** when some sensation or voluntary movement remains there, which means some messages still cross the injury (Snider et al., n.d.). Incomplete injuries were more common than complete ones in the Canadian registry (Praxis Spinal Cord Institute, 2024). Table 32.2 summarizes the function usually expected at each level after a motor-complete injury, in which no voluntary movement is kept below the level (Consortium for Spinal Cord Medicine, 2026).

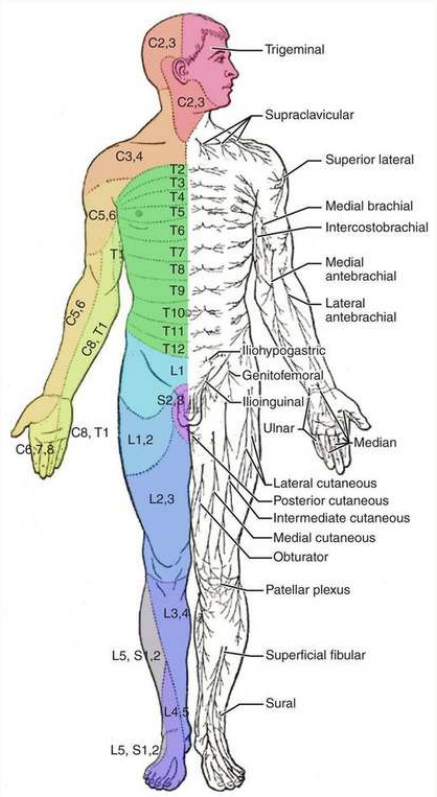

Figure 32.2 Human dermatome map showing the cutaneous sensory territories supplied by spinal nerves C2 through S5, used alongside key muscle testing to determine the neurologic level of spinal cord injury. (credit: "1611 Dermatomes-02" by OpenStax Anatomy and Physiology/Wikimedia Commons, CC BY 4.0)

Table 32.2 Spinal cord injury level and expected function after a motor-complete injury (Consortium for Spinal Cord Medicine, 2026; Jang, 2020; Peterson & Delparte, 2022)

Level	Muscles and function kept	Breathing	Main care needs
C1 to C4	Face and neck muscles; talking, chewing and sipping; partial diaphragm and shoulder shrug at C3 to C4	Diaphragm weak or not working; a ventilator is often needed	Airway and ventilator care; suctioning; full assistance with care; power wheelchair with head, chin or breath controls; autonomic dysreflexia risk
C5	Shoulder movement and elbow bending (biceps)	Diaphragm works, but chest and abdominal muscles do not; weak cough and lower vital capacity	Assisted cough; full help with bladder and bowel care; mechanical lift, or a transfer board with help, for transfers; autonomic dysreflexia risk
C6	Wrist extension, which allows a tenodesis grasp	As for C5	Some help with bladder and bowel care; may manage some tasks with adaptive equipment; autonomic dysreflexia risk
C7 to C8	Elbow straightening (triceps), wrist and finger movement	As for C5, with weak cough	Independent bladder and bowel care with adaptive equipment; manual wheelchair; autonomic dysreflexia risk
T1 to T12	Arms fully; trunk control improves the lower the level; abdominal muscles from T7 down	Breathing and cough improve the lower the level	Manual wheelchair; skin and pressure care; autonomic dysreflexia risk at T6 and above
L1 to S1	Hip and knee movement; lower levels add ankle and foot movement	Main breathing muscles spared	May walk with aids and braces; wheelchair for long distances; bladder, bowel and skin care

GOING DEEPER

Classifying Spinal Cord Injury (ISNCSCI and the ASIA Impairment Scale)

Required for RN students; optional for PN students.

The **International Standards for Neurological Classification of Spinal Cord Injury (ISNCSCI)**, maintained by the American Spinal Injury Association (ASIA), describe how to examine and classify SCI. The current standard is the 2019 revision (American Spinal Injury Association, n.d.; Rupp et al., 2021). The examiner tests light touch and pinprick in each dermatome, key muscles on both sides, deep anal pressure and voluntary anal contraction. The neurologic level of injury is the higher of the sensory and motor levels (Snider et al., n.d.).

The **ASIA Impairment Scale (AIS)** grades completeness (Snider et al., n.d.):

- **AIS A, complete:** no sensory or motor function preserved in the lowest sacral segments, S4–S5.
- **AIS B, sensory incomplete:** sensation, but not motor function, is preserved below the neurologic level and includes S4–S5, and no motor function is preserved more than three levels below the motor level on either side.
- **AIS C, motor incomplete:** motor function is preserved below the level (voluntary anal contraction, or, in a sensory incomplete injury, some motor function more than three levels below the motor level), and less than half of the key muscles below the neurologic level have a muscle grade of 3 or more (movement against gravity).
- **AIS D, motor incomplete:** motor incomplete as in AIS C, but half or more of the key muscles below the neurologic level have a muscle grade of 3 or more.
- **AIS E, normal:** sensation and motor function test normal in all segments in a person who had deficits from a documented SCI.

A label such as "C5 AIS B" gives level and completeness at a glance; repeat examinations track change.

Early Care

Spinal motion restriction. Ontario's paramedic standards direct paramedics to consider **spinal motion restriction**, keeping the spine as still as possible, for any patient who may have a spine or spinal cord injury (Ontario Ministry of Health, 2023). Risk criteria include spine tenderness, neck or back pain, neurologic signs or symptoms, an altered level of consciousness, suspected intoxication, a distracting painful injury, a deformity of the spine and a high-energy mechanism, which for a person aged 65 or older includes a fall from standing height. The standard uses a cervical collar, applied before moving the patient when possible, and secures the patient to the stretcher. Patients are log rolled off extrication devices when enough staff are present, and rigid spine boards are removed as soon as it is safe (Ontario Ministry of Health, 2023; Figure 32.3).

In hospital, the nurse continues these precautions until a physician or NP documents that the spine is cleared or stable. A **log roll** turns the patient with the head, shoulders, trunk and hips moving together as one unit, so that the spine does not twist; it needs enough trained staff, and employer policy sets the technique. Skin under and around a cervical collar is checked as policy directs, because medical devices can cause pressure injuries (Chapter 35). Spinal fractures and surgery are covered in Chapter 33.

Breathing. The diaphragm, the main muscle for breathing in, is supplied mainly by spinal nerves C3 to C5 through the phrenic nerve. The intercostal and abdominal muscles, supplied by thoracic nerves, help force air out and produce a strong cough (Jang, 2020). Injuries in the cervical and upper thoracic cord therefore reduce lung volumes, vital capacity and cough strength, and the higher the injury, the greater the need for a ventilator (Jang, 2020). Between 36% and 83% of people with acute SCI develop respiratory complications. The most common are respiratory failure and atelectasis, and pneumonia is more frequent with higher and more severe injuries (SCIRE Professional, 2023). Intense secretion management has been suggested as the key to prevention, and chest percussion, postural drainage and manually assisted coughing have been reported to reduce deaths from lung complications (SCIRE Professional, 2023). In a **manually assisted cough**, the nurse or a trained caregiver presses on the abdomen or chest just as the patient breathes out to cough; machines can also assist a cough (Jang, 2020). An abdominal binder puts pressure around the abdomen to help keep the diaphragm in a better position for breathing (Jang, 2020). The nurse reports at once any increase in breathing effort, a weaker cough, thicker or more secretions, or a fall in oxygen saturation. Airway management and ventilation are covered in Chapter 15.

Spinal shock and neurogenic shock. Two terms are often confused. **Spinal shock** is a temporary state, beginning immediately after SCI, in which reflexes carried by the spinal cord are lost below the injury (SCIRE Community, 2024). It is a change in reflexes, not a circulation problem. **Neurogenic shock** is low blood pressure together with a slow heart rate, with no other cause, after a cervical or

Figure 32.3 A rigid cervical collar applied to restrict cervical spine motion until spinal injury is ruled out or stabilized (upper facial profile pixelated). (credit: modification of "LateralCollar" by James Heilman, MD/Wikimedia Commons, CC BY-SA 3.0)

high thoracic SCI; the injury suddenly cuts sympathetic nerve output, so blood vessels relax and the heart slows (SCIRE Professional, 2022). The slow heart rate helps tell it apart from shock caused by blood loss, in which the heart rate is usually fast. Shock is managed as described in Chapter 6. An international guideline panel suggests keeping the mean arterial pressure (MAP) at no less than 75 to 80 mm Hg, and not actively raising it above 90 to 95 mm Hg, for three to seven days after acute SCI; both are weak recommendations based on very low-quality evidence (Kwon et al., 2024).

Venous thromboembolism. Immobility after SCI slows blood flow in the legs. Deep vein thrombosis has its highest incidence in the first three months after injury, with most events in the first two weeks, and it can lead to a fatal pulmonary embolism; prevention uses medicines and mechanical methods (Mirkowski et al., 2020). Venous thromboembolism (VTE) prevention is covered in Chapter 19.

Autonomic Dysreflexia

Autonomic dysreflexia (AD) is a sudden rise in blood pressure of 20 to 40 mm Hg above the person's usual level, triggered by an irritating stimulus below the level of SCI (Alberta Health Services [AHS], 2021). It typically occurs with injuries at T6 or above (AHS, 2021). The stimulus sets off a strong reflex that narrows blood vessels below the injury, and because messages from the brain cannot pass the injury, the reflex continues until the cause is removed. Most people at risk have their first episode within six months of injury (Peterson & Delparte, 2022). Untreated AD can cause a stroke, a seizure or death (AHS, 2021).

Triggers. A full bladder is the most common cause, including a blocked or kinked catheter. Other causes are a full bowel or constipation, pressure on the skin from lying or sitting on something hard, tight clothing or devices, skin wounds and ingrown toenails, infections, menstrual cramps, sexual activity and procedures (AHS, 2021; Peterson & Delparte, 2022).

Recognizing AD. Signs include a pounding headache, flushing and sweating above the injury, pale or cool skin and goosebumps below it, blurred vision, a stuffy nose, anxiety and a slow heart rate (AHS, 2021; Peterson & Delparte, 2022). Because flushing is easier to see on some skin tones than others, the nurse does not rely on colour alone: the patient's report, sweating and the blood pressure reading matter more. Many people with an injury at T6 or above have a usual systolic pressure of about 90 to 110 mm Hg, so a systolic reading above 130 mm Hg, which would not alarm most clinicians, can be a sign of AD (Peterson & Delparte, 2022). Knowing the patient's baseline is essential.

First actions. AD is an emergency, and any nurse who recognizes it acts at once. Alberta's adult protocol lists these steps in order (AHS, 2021):

- Ask the patient whether they know what is causing it; many people with SCI recognize their own triggers.
- Sit the patient up at 90 degrees; lowering the legs also helps lower blood pressure (Peterson & Delparte, 2022).
- Remove the cause if it is known, and loosen tight clothing, straps and devices.
- Check the blood pressure every 2 to 5 minutes.
- Check the bladder: look for a kinked, clamped or blocked catheter and a full drainage bag, or empty the bladder as ordered.
- Check the bowel for stool, gently and following the employer's protocol.

- Check the skin for pressure areas, wounds and anything tight.

The nurse notifies the physician or NP (and the RN, when an RPN holds the assignment) early, and calls the medical emergency or rapid response team if the blood pressure does not come down or the patient becomes unresponsive (AHS, 2021). Medicines to lower blood pressure are given only as ordered. After the episode, blood pressure is checked often and the nurse watches for low blood pressure (Peterson & Delparte, 2022). The nurse documents the trigger and teaches prevention.

Teaching. People at risk, and their families and caregivers, learn the signs, the first steps and their usual blood pressure. They are encouraged to carry a wallet card that lists these, and to show it to health care staff, who may not know about AD (Peterson & Delparte, 2022). Prevention includes regular bladder and bowel routines, catheter tubing that drains freely, loose clothing, regular skin checks and early treatment of infections (Peterson & Delparte, 2022).

CLINICAL SAFETY

Autonomic Dysreflexia Is an Emergency

A person with an SCI at T6 or above who reports a pounding headache, or who looks flushed and sweaty above the injury, may have dangerously high blood pressure (AHS, 2021).

- **Do not lay the patient flat.** Sit them up at 90 degrees and lower the legs (AHS, 2021; Peterson & Delparte, 2022).
- **Check the blood pressure at once and every 2 to 5 minutes.** Compare it with the person's usual reading, which is often low; a "normal-looking" pressure may be high for them (AHS, 2021; Peterson & Delparte, 2022).
- **Look for the cause, starting with the bladder,** then the bowel, then the skin and clothing (AHS, 2021).
- **Call for help early.** Notify the physician or NP and the RN, and activate the emergency response if the pressure does not fall or the patient becomes unresponsive (AHS, 2021).
- **Watch afterward** for low blood pressure once the cause is removed (Peterson & Delparte, 2022).
- **Record the person's usual blood pressure and known triggers** in the care plan so that every shift can act quickly.

Ongoing Care and Rehabilitation

After the acute phase, care shifts to preventing complications and building independence.

- **Bladder:** People with SCI often need a planned bladder program to empty the bladder regularly. A full bladder is the most common trigger of AD (AHS, 2021). Catheters and urinary retention are covered in Chapter 28.
- **Bowel:** A regular bowel routine prevents constipation, accidents and AD (Peterson & Delparte, 2022). Bowel programs are covered in section 25.1.
- **Skin:** Loss of sensation and movement puts skin at high risk. Regular position changes, pressure redistribution and daily skin checks are taught in Chapter 35.
- **Temperature:** People with tetraplegia or an injury at T6 or above usually have more trouble regulating body temperature than people with lower injuries. People with tetraplegia can have episodes of low body temperature in a normal room and are more affected by cold (SCIRE Professional, 2025). The nurse checks temperature, adjusts covers and room temperature, and teaches the person to avoid extremes.
- **Spasticity: Spasticity** is increased muscle tone with involuntary spasms and overactive reflexes. It affects up to three-quarters of people with SCI, especially those with cervical or incomplete injuries (SCIRE Community Team, 2017). It can help with transfers and standing but can also cause pain, contractures and skin breakdown. A sudden or unexplained change may point to a new health problem, most often a bladder infection or skin breakdown, so the nurse looks for a cause (SCIRE Community Team, 2017).
- **Sexuality and fertility:** These are important parts of rehabilitation and are covered in Chapter 29.
- **Mood and adjustment:** Adjusting to SCI takes time. The nurse asks about mood, sleep, substance use and thoughts of self-harm, and helps the person reach mental health care and peer support; the Consortium for Spinal Cord Medicine publishes a guideline on mental health disorders, substance use and suicide in adults with SCI.

Rehabilitation and community living. Rehabilitation teams help each person reach the function expected for their level and completeness of injury (Consortium for Spinal Cord Medicine, 2026). In the Canadian registry, 90% of people with non-traumatic

SCI went home to the community after rehabilitation, and 44% developed at least one secondary complication while in rehabilitation (Praxis Spinal Cord Institute, 2024). Living in the community depends on accessible housing, transportation, equipment, attendant care and work. Accessible care, including asking the person how they want to be moved and helped, is taught in Chapter 2. People with SCI are the experts on their own bodies and routines, and the nurse plans care with them.

32.3 Multiple Sclerosis

Multiple sclerosis (MS) is a long-term autoimmune disease that affects the central nervous system (CNS). Its course is hard to predict, and many people move between periods of new or worse symptoms and periods of recovery (Public Health Agency of Canada [PHAC], 2024). MS is usually diagnosed in early adulthood, at a time of study, work and raising children. Nurses often meet people with MS when they are admitted for another reason.

What Happens in MS

In MS, the immune system damages **myelin**, the fatty covering that insulates nerve fibres in the optic nerves, brain and spinal cord (PHAC, 2024). This damage is called **demyelination**. Without intact myelin, nerve signals travel slowly or not at all, so the symptoms depend on where the damaged areas lie. A lesion in the optic nerve blurs vision; one in the spinal cord can cause weakness, numbness or bladder problems. On magnetic resonance imaging (MRI), new or enlarging lesions are one sign of active disease (Oh et al., 2025).

Course of the disease. MS Canada (then the Multiple Sclerosis Society of Canada, 2021) describes several forms:

- **Clinically isolated syndrome (CIS):** a single episode of symptoms that suggests MS.
- **Radiologically isolated syndrome (RIS):** MRI findings that strongly suggest MS in a person with no symptoms.
- **Relapsing-remitting MS (RRMS):** clear relapses followed by recovery. It is the most common diagnosis at first; about 90% of Canadians with MS are first diagnosed with this form.
- **Secondary progressive MS (SPMS):** a later phase that most people with RRMS eventually enter, with fewer relapses and gradual worsening.
- **Primary progressive MS (PPMS):** steady worsening from the start, usually without clear relapses. About 10% of people with MS are diagnosed with this form.

A **relapse** is the appearance of new symptoms, or a clear worsening of existing ones, lasting at least 24 to 48 hours when no outside factor such as infection, fever, heat, stress or fatigue explains it (Multiple Sclerosis Society of Canada, 2021). Between relapses, the person is in **remission**, which may last years.

Risk factors. The cause of MS is not fully understood. Genes are thought to interact with lifestyle (for example, smoking and obesity) and with the environment (for example, low vitamin D levels) (PHAC, 2024). Infection with Epstein–Barr virus in childhood is linked to about 10 times the usual risk, and a past episode of infectious mononucleosis to about 20 times the risk. A parent, sibling or child of a person with MS has a risk of about 3% to 5%, compared with about 0.25% in the general population (Multiple Sclerosis Society of Canada, 2021). About 7 in 10 Canadians living with MS are women (PHAC, 2024). Canadian data appear in the Canadian Context box.

Diagnostics. A neurologist makes the diagnosis from the history, the neurologic examination and MRI evidence of lesions in the CNS. Other causes are ruled out first.

Living With MS

Common symptoms. PHAC (2024) lists walking problems, weakness and poor coordination; vision changes; pain, tingling and numbness; fatigue; changes in mood and thinking; and bladder and bowel problems. Fatigue affects about 90% of people with MS, and bladder dysfunction about 80% (Multiple Sclerosis Society of Canada, 2021). Spasticity, muscle stiffness with involuntary spasms, can make transfers and sleep difficult. Fatigue, pain and cognitive changes are invisible to others, so the nurse asks about them directly.

Heat and pseudo-relapse. A **pseudo-relapse** is a short-lived return or worsening of symptoms the person has had before. It is triggered by a rise in body temperature or by stress on the body, such as fever, infection, hot baths, sun, exercise, fatigue or strong emotion. No new inflammation is involved, and the symptoms settle as body temperature returns to normal (Multiple Sclerosis Society of Canada, 2021). The nurse therefore looks for a cause, such as a urinary tract infection, before assuming a relapse. Fever is reported and treated as ordered, and cool rooms and fans help.

When to report. People with MS are taught to contact their MS team about new symptoms or symptoms that clearly worsen and last more than a day or two. They also report changes in bladder function or a suspected urinary tract infection, new pain, and sexual concerns (Multiple Sclerosis Society of Canada, 2021). Routine visits with the MS team usually happen every 6 to 12 months. Corticosteroids, such as prednisone by mouth or methylprednisolone intravenously, can lessen a relapse and speed recovery, but long-term use is avoided because of side effects (Multiple Sclerosis Society of Canada, 2021).

Disease-modifying therapies. MS cannot be cured, but diagnosing and treating it early can make relapses fewer and milder, slow the build-up of disability and progression, and ease symptoms (PHAC, 2024). A **disease-modifying therapy (DMT)** is a long-term medication that changes the course of MS by acting on the immune system. By 2024, Health Canada had authorized 18 DMTs. Examples include fingolimod, siponimod, ozanimod and cladribine, taken by mouth, and the monoclonal antibodies ocrelizumab, ofatumumab, alemtuzumab and natalizumab, given by infusion or injection (Oh et al., 2025). The neurologist chooses the drug with the person, considering disease activity, safety and plans for pregnancy (Oh et al., 2025). Nursing points for these drugs are summarized with other neurologic medicines in a table in section 32.6.

Because DMTs act on the immune system, infection is the main safety concern. Natalizumab is an example. Its Canadian monograph carries a boxed warning about **progressive multifocal leukoencephalopathy (PML)**, a rare and serious brain infection caused by the John Cunningham (JC) virus. Natalizumab is available only through a controlled distribution program, and the risk rises with longer treatment, with prior immunosuppressant use and when antibodies to the JC virus are present (Biogen Canada, 2025). The monograph asks that patients be observed during each infusion and for an hour after it ends, to watch for reactions. It also warns of herpes infections of the brain and its coverings. Signs of PML develop over days to weeks: weakness on one side of the body, clumsiness, vision changes, and changes in memory, thinking or personality that the person may not notice. Family members are therefore included in teaching (Biogen Canada, 2025).

Rehabilitation and self-management. Physiotherapy and occupational therapy help with mobility, spasticity, fatigue and safety at home and work. People with MS live, on average, about 95% of a normal life expectancy (Multiple Sclerosis Society of Canada, 2021), so the focus is on living well for decades. MS Canada's MS Navigators offer information and support by phone and email.

Care in hospital. When a person with MS is admitted, the nurse:

- records the DMT, the date of the last dose or infusion and the person's usual routines, and asks the prescriber whether to continue the DMT;
- looks for infection, and reports fever early, since it can worsen symptoms;
- follows the person's bladder and bowel routines (Chapter 28; section 25.1) and checks the skin (Chapter 35);
- plans activity and rest to manage fatigue, and assesses fall risk (Chapter 8);
- screens for low mood and asks about pain (Chapter 5); and
- asks what the person needs to stay independent, such as mobility aids or more time for tasks (Chapter 2).

CANADIAN CONTEXT

Multiple Sclerosis in Canada

Canadian numbers on MS depend on how MS is counted.

- **Surveillance data:** PHAC's Canadian Chronic Disease Surveillance System (CCDSS) uses health-care records. In fiscal year 2021–2022, about 290 in every 100,000 adults (aged 20 and older) in Canada had MS. About 7 in 10 were women. Of new diagnoses, about 65% were in people aged 20 to 49 (PHAC, 2024).
- **Trends:** From 2011–2012 to 2021–2022, the proportion of adults with MS grew on average 1.5% per year (from 0.25% to 0.29%), while the rate of new diagnoses stayed flat. People may be diagnosed younger, living longer, or both (PHAC, 2024).

Data for Quebec, the Northwest Territories and Yukon were not available, New Brunswick and Saskatchewan data were not available for 2021–2022, and PHAC cautions that the COVID-19 pandemic affected 2021–2022 measures.

- **Survey-based estimates:** MS Canada estimates that about 90,000 people in Canada have MS (Multiple Sclerosis Society of Canada, 2021). It notes that survey-based counts may overestimate the number, while CCDSS counts rely on health-care records (MS Canada, n.d.).

For nurses, the message is the same: MS is common, and most people with it are working-age adults. Access to MS clinics, infusion centres and rehabilitation is harder in rural, remote and northern communities, and travel adds cost and fatigue. Virtual visits and local primary care partners help close the gap.

32.4 Parkinson Disease

Parkinson disease (PD) is a chronic, progressive neurologic disease that affects movement and many other body systems (Grimes et al., 2019). More than 100,000 Canadians live with PD, and about 25 more are diagnosed each day (Parkinson Canada, 2021). Most are older adults, and many are admitted to hospital for other reasons, such as a fall, a fracture or an infection. How the nurse handles their medications can change the course of the whole stay.

Signs and Course

PD is best known for its effects on movement. In a deep part of the brain called the substantia nigra, nerve cells that make **dopamine**, a chemical messenger needed for smooth movement, are lost. Parkinson Canada stresses that PD is a multi-system disease: the clumps of abnormal protein seen in PD, called Lewy bodies, may first appear in the lower brain stem and the nerves of smell rather than in the substantia nigra (Parkinson Canada, 2010).

Motor signs. The classic signs are tremor, rigidity, slow movement and poor balance. The diagnosis is clinical: neurologists look for two of the three main signs plus a response to levodopa (Parkinson Canada, 2010; Figure 32.4).

- **Resting tremor:** rhythmic shaking, often of one hand, that is present at rest.
- **Rigidity:** stiffness of the muscles when a limb is moved by someone else.
- **Bradykinesia:** slowness of movement, with small steps, a soft voice and small handwriting.
- **Poor balance:** a higher risk of falls as the disease advances.

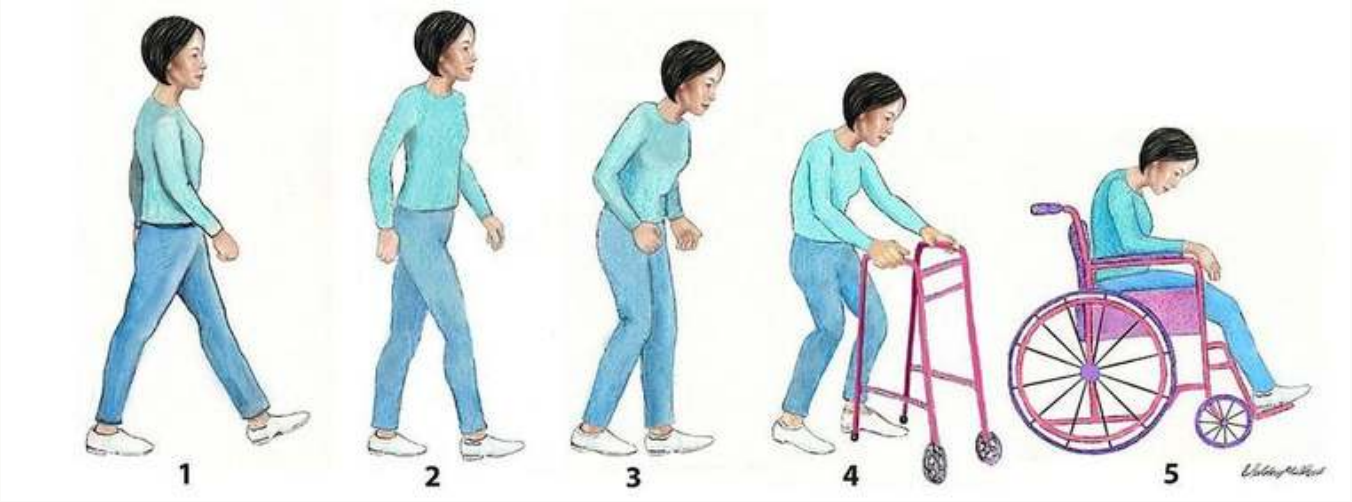

Figure 32.4 Progression of posture, gait and mobility across the five stages of Parkinson disease on the Hoehn and Yahr scale. (credit: "5 Stages of Parkinson's Disease, Hoehn & Yahr Scale" by Bbmime/Wikimedia Commons, CC BY 4.0)

Non-motor symptoms. People with PD are often more disabled by non-motor symptoms than by motor ones (Parkinson Canada, 2010). These include loss of smell, constipation, depression, anxiety, apathy, restless legs, swallowing problems and mild cognitive impairment. Some, such as acting out dreams during sleep (rapid eye movement [REM] sleep behaviour disorder), low mood and

loss of smell, often appear years before the tremor (Parkinson Canada, 2010). **Orthostatic hypotension**, a drop in blood pressure on standing that causes dizziness or fainting, is common (Grimes et al., 2019). Later, dementia and psychosis with hallucinations may develop (Grimes et al., 2019).

Treatment over time. Levodopa, combined with carbidopa, remains the most effective medication for motor symptoms, and the Canadian guideline sees no reason to delay it once symptoms are bothersome (Grimes et al., 2019). Over years, people often notice **wearing off**, the return of symptoms before the next dose is due, and **dyskinesia**, involuntary writhing movements. Dyskinesia was the most frequent adverse reaction reported in the levodopa-carbidopa controlled-release monograph (Pharmascience, 2020). Levodopa can also cause orthostatic hypotension, hallucinations and confusion, and sudden sleep during daily activities, sometimes without warning (Pharmascience, 2020). A speech-language pathologist helps with swallowing, speech and drooling, and a physiotherapist with balance (Grimes et al., 2019). For carefully selected people with severe motor fluctuations despite the best medication plan, **deep brain stimulation**, in which electrodes are placed in the brain, is the surgical treatment of choice (Grimes et al., 2019).

Care in Hospital

Medications on time, every time. Parkinson Canada's ACT on Time campaign asks that people with PD receive their medications on time in every setting: at home, in the emergency department, in hospital and in long-term care. The person's schedule may not match the unit's medication rounds. Late or missed doses can leave symptoms uncontrolled and lengthen recovery (Parkinson Canada, 2019, 2021). Levodopa-carbidopa has a half-life of about 2 hours, so even a short delay matters (Emergency Care BC, 2023). Canadian data show how often this goes wrong. In one Canadian hospital study of 104 admissions of people with PD, 12.9% of scheduled doses were given at the wrong time and 8.7% were omitted, and 88% of admissions involved one or more doses given over 60 minutes off schedule (Cowley et al., 2021).

The nurse:

- confirms the exact home times with the person or family on admission, not just the number of doses a day;
- enters those clock times in the medication record and gives each dose on time, within the window that employer policy sets;
- supports self-administration where policy allows, and asks to see the person's medication card; Parkinson Canada's Medical Alert Card lists current medications and medications to avoid (Parkinson Canada, 2019); and
- reports any dose that cannot be given.

Never stopping levodopa suddenly. A rapid dose cut or withdrawal of PD medication can cause a reaction like neuroleptic malignant syndrome, with rigidity, fever, altered consciousness and unstable vital signs (Pharmascience, 2020). It is rare but dangerous; treatment includes restarting dopamine medication (Emergency Care BC, 2023).

NPO and surgery. When a person with PD must have nothing by mouth (NPO), the nurse does not simply hold the medications. The nurse contacts the prescriber, the anesthesia team and the pharmacist early to plan how doses will continue around the procedure, and confirms the plan before the first dose is due (Chapter 7). If swallowing is unsafe, the nurse asks about another route or form, and checks with the pharmacist before crushing any tablet (section 24.3).

Drugs that block dopamine. Many antipsychotics and the antiemetic metoclopramide block dopamine and should be avoided (Emergency Care BC, 2023). The levodopa-carbidopa monograph warns that dopamine blockers, such as the phenothiazines, the butyrophenones and risperidone, can blunt the effect of levodopa, and that metoclopramide may worsen disease control (Pharmascience, 2020). The metoclopramide monograph states that people with PD should receive it cautiously, if at all (JAMP Pharma, 2023). Before giving a new antiemetic, sedative or antipsychotic, the nurse checks it against these lists, questions any dopamine blocker, and asks the prescriber or pharmacist for an alternative. For psychosis in PD, the Canadian guideline names quetiapine as possibly useful and clozapine as useful with monitoring (Grimes et al., 2019). Iron supplements and high-protein meals can reduce levodopa absorption (Pharmascience, 2020), so the nurse asks the pharmacist how to time them.

Delirium, falls and swallowing. Hospital stays bring new risks. Hallucinations and confusion may come from the disease, from medications or from **delirium**; any new change is reported and screened for (Chapter 8). The nurse checks orthostatic vital signs, helps the person rise slowly and keeps aids within reach to prevent falls (Chapter 8). Swallowing is watched closely, since missed doses and aspiration are linked (Parkinson Canada, 2011; section 24.3).

PRACTICE STORY

Every Dose on Time

Names and details are fictional; this is a composite story.

Nurse: Chidinma Adeyemi, RN. Years in practice: 6. Setting: surgical unit, Ontario.

Mr. Henri Lavoie, 76, came to our unit after surgery to repair a broken hip. He has lived with Parkinson disease for 11 years. His wife, Monique, handed me a laminated card at the bedside. It listed his levodopa-carbidopa at 0600, 0930, 1300, 1630 and 2000, and two medicines he should never be given.

The admission orders said "four times daily," and the system had set the doses at 0900, 1300, 1700 and 2100. His 0600 dose had been held for surgery, and it was already 1100. He lay stiff, his voice was a whisper, and he could not roll to let me check his skin. Monique said, "This is not him. He's frozen."

I called the surgical resident and the pharmacist. We restarted his levodopa at once, and the resident rewrote the order to match his clock times. I entered each time in the record and added a note to the whiteboard and the handover sheet. By 1300, Henri could turn with help and swallow his tablets with applesauce, as the speech-language pathologist had advised.

That evening he was nauseated, and the order set included metoclopramide. Metoclopramide was on Monique's card. I held it and paged the resident, explaining that it blocks dopamine and can worsen Parkinson symptoms. The pharmacist suggested another antiemetic, and the resident ordered it. His nausea settled.

Before I went home, I talked with the night nurse about the 2000 dose and the 0600 dose, and asked for the 0600 dose to be planned with the physiotherapy session. The next morning, Henri stood at the bedside with the physiotherapist. Monique told me it was the first time a hospital had followed his card.

Reflect: Which parts of this plan could an RPN on the same unit lead, and when should the RPN involve the RN? How do authority, competence and context apply when a nurse holds a prescribed medication and asks for a new order?

32.5 Myasthenia Gravis and Guillain–Barré Syndrome

Myasthenia gravis and Guillain–Barré syndrome both cause weakness through an immune attack outside the brain and spinal cord. Myasthenia gravis is a chronic disease with flare-ups; Guillain–Barré syndrome is an acute illness from which most people recover. In both, the main danger is weakness of the muscles that breathe and swallow (Table 32.3).

Myasthenia Gravis

Myasthenia gravis (MG) is an autoimmune disease in which antibodies attack acetylcholine receptors, or related proteins, on the muscle side of the **neuromuscular junction**, where a nerve passes its signal to a muscle (Sheikh et al., 2021). Fewer working receptors mean the signal weakens with repeated use. The result is weakness that gets worse with activity and improves with rest.

Manifestations. MG often affects the eyes first. **Ptosis**, a drooping upper eyelid, and double vision are common. Weakness of the face, jaw and throat (bulbar weakness) causes a nasal voice, tiring while chewing, choking and trouble swallowing. Limb weakness and weakness of the breathing muscles may follow. Symptoms are often worse late in the day or after effort, such as a long meal (Figure 32.5).

Figure 32.5 Asymmetric ptosis (drooping upper eyelid, right greater than left) and strabismus causing diplopia in a person with myasthenia gravis attempting to open the eyes. (credit: "DiplopiaMG1" by James Heilman, MD/Wikimedia Commons, CC BY-SA 3.0)

Myasthenic crisis. International consensus guidance defines a **myasthenic crisis** as weakness that worsens until the person needs intubation, or noninvasive ventilation to prevent intubation. An impending crisis is rapid worsening that, in the treating physician's opinion, could lead to crisis within days to weeks (Sanders et al., 2016). The 2020 update of this guidance did not change these definitions (Narayanaswami et al., 2021). Impending crisis calls for hospital admission and close watching of breathing and swallowing. A crisis calls for intensive care or a step-down unit (Sanders et al., 2016).

Triggers and medications. Infection, surgery and some medications can worsen MG. A review of drugs linked to MG lists fluoroquinolone and macrolide antibiotics, aminoglycosides, magnesium, beta-blockers, calcium channel blockers, some antiarrhythmics, neuromuscular blockers used in anesthesia and botulinum toxin. Immune checkpoint inhibitors used in cancer care can trigger MG for the first time or worsen existing MG (Narayanaswami et al., 2021; Sheikh et al., 2021). The review advises avoiding fluoroquinolones and macrolides when a safer alternative exists and using magnesium with extreme caution (Sheikh et al., 2021). High starting doses of corticosteroids can cause a short-term worsening of weakness (Sanders et al., 2016; Sheikh et al., 2021). When a new order arrives, the nurse checks it against these classes and asks the prescriber or pharmacist if it is on the list. The nurse then watches swallowing and breathing closely after any change.

Pyridostigmine. Pyridostigmine, a cholinesterase inhibitor, should be part of the first treatment for most people with MG (Sanders et al., 2016). It lets acetylcholine act longer at the junction. The Canadian monograph states that tablets are swallowed whole and not crushed, and that a larger share of the daily dose may be timed for periods when the person tires more easily, such as meals (Bausch Health, 2019). The nurse gives each dose on time and works with the team so that meals fall when the medication is working. Its cholinergic effects include more saliva and airway secretions, sweating, cramps and diarrhea. Too much can itself cause weakness, a **cholinergic crisis**. Because a myasthenic crisis and a cholinergic crisis both cause severe weakness but need very different treatment, the nurse reports any worsening rather than giving an extra dose (Bausch Health, 2019).

Other treatments. For severe generalized MG and crisis, **plasma exchange** (removing the antibody-containing plasma and replacing it) and **intravenous immune globulin (IVIG)** are probably equally effective, although expert opinion favours plasma exchange for faster effect in crisis (Sanders et al., 2016). Corticosteroids and other immune-suppressing drugs are used for long-term control.

Guillain–Barré Syndrome

Guillain–Barré syndrome (GBS) is an acute immune attack on the peripheral nerves. About two-thirds of patients recall an infection during the 6 weeks before the weakness starts. *Campylobacter jejuni*, a common cause of diarrheal illness, is one of six infections linked to GBS, along with cytomegalovirus, hepatitis E virus, *Mycoplasma pneumoniae*, Epstein–Barr virus and Zika

virus. A recent infection is not required for the diagnosis (Leonhard et al., 2019). Worldwide, GBS affects about 1 to 2 people per 100,000 each year. It is most common between ages 50 and 70, and men are about 1.5 times more likely to be affected (van Doorn et al., 2023).

Manifestations. GBS usually starts with tingling or numbness in the feet and hands. Weakness then begins in the legs and climbs to the arms and the muscles of the face and throat; this pattern is called **ascending paralysis** (Leonhard et al., 2019). Weakness of both sides of the face is common. Reflexes are reduced or absent in most patients when they arrive and in almost all at the worst point, a finding called **areflexia**. Pain is common, often in the back and limbs. **Autonomic dysfunction**, damage to the nerves that control heart rate, blood pressure, bowel and bladder, causes swings in blood pressure, abnormal heart rhythms and urinary retention. Most patients reach their worst point within 2 weeks (Leonhard et al., 2019). Within the first week after admission, up to 22% need a ventilator (Leonhard et al., 2019). Respiratory failure can develop without breathlessness, so the nurse cannot rely on the patient's report alone.

Diagnostics. The diagnosis rests on the pattern of weakness and reflexes, supported by nerve conduction studies (Leonhard et al., 2019).

Nursing care. The nurse measures breathing strength as ordered (see the Going Deeper box), watches swallowing and cough, and monitors heart rhythm, blood pressure, and bladder and bowel function (Leonhard et al., 2019). Reasons to involve critical care include worsening breathing, severe swings in heart rate or blood pressure, severe trouble swallowing, a weak cough and rapidly spreading weakness (Leonhard et al., 2019). The nurse escalates early using SBAR (Chapter 6).

A patient who cannot move needs prevention of deep vein thrombosis (Chapter 19), pressure injuries (Chapter 35) and hospital-acquired infections (Leonhard et al., 2019). Facial weakness can stop the eye from closing, so the eyes are protected from corneal damage. Positioning and range-of-motion exercises help prevent contractures. Pain, hallucinations, anxiety and depression are common, so the nurse asks about them, especially when the patient cannot speak easily (Leonhard et al., 2019). Most patients stay fully conscious and can see and hear. The nurse explains every procedure, sets up a call system the patient can use and speaks to the patient, not about the patient, at the bedside.

Treatment. The guideline from the European Academy of Neurology and Peripheral Nerve Society strongly recommends IVIG as soon as possible for patients who cannot walk unaided and are within 2 weeks of onset, or plasma exchange within 4 weeks. It recommends against corticosteroids (van Doorn et al., 2023).

Recovery. About 80% of patients walk independently again by 6 months. Between 3% and 10% die, mostly from heart and breathing complications, and many deaths happen during the recovery phase, so monitoring continues even when the patient is improving (Leonhard et al., 2019). In 6% to 10% of patients, weakness worsens again within 2 months after first improving or stabilizing with treatment (Leonhard et al., 2019). Physiotherapy, occupational therapy and speech therapy start during the hospital stay and continue for more than 6 months when needed (van Doorn et al., 2023).

Table 32.3 Chronic and acute neuromuscular and neurologic disorders compared (Grimes et al., 2019; Leonhard et al., 2019; Multiple Sclerosis Society of Canada, 2021; Sanders et al., 2016; Shoesmith et al., 2020)

Disorder	What goes wrong	Key signs	Danger signs to report	Nursing focus
Multiple sclerosis	Immune damage to myelin in the optic nerves, brain and spinal cord	Fatigue, vision changes, weakness, numbness, spasticity, bladder problems	New or worse symptoms lasting more than 24 to 48 hours; fever; signs of infection on a DMT	Look for infection or heat as a cause; keep routines; manage fatigue; teach when to report
Parkinson disease	Loss of dopamine-making nerve cells and wider nervous system changes	Tremor, rigidity, slow movement, poor balance; constipation, low mood, low blood pressure on standing	Rigidity with fever and confusion after missed doses; new confusion or hallucinations; falls; choking	Give medications at the person's own times; avoid dopamine blockers; prevent falls and aspiration
Myasthenia gravis	Antibodies block signals at the neuromuscular junction	Weakness that worsens with use; drooping eyelids; double vision; tiring while chewing	Trouble swallowing saliva; weak cough; shortness of breath; falling breathing measures	Time pyridostigmine on schedule; check new drug orders; monitor breathing and swallowing

Disorder	What goes wrong	Key signs	Danger signs to report	Nursing focus
Guillain–Barré syndrome	Acute immune attack on peripheral nerves, often after an infection	Tingling, then weakness rising from the legs; lost reflexes; pain	Falling vital capacity; weak cough; swallowing trouble; swings in heart rate or blood pressure	Measure breathing strength; monitor heart rhythm; prevent clots and pressure injuries; explain and reassure
Amyotrophic lateral sclerosis	Loss of motor nerve cells in the brain and spinal cord	Weakness, muscle wasting, twitching, stiffness; slurred speech	Breathlessness lying flat; weak cough; choking; weight loss	Support breathing and nutrition decisions; communication tools; advance care planning

GOING DEEPER

Watching the Breathing Muscles

Required for RN students; optional for PN students.

In MG and GBS, the lungs are usually healthy; the problem is the pump. Bedside measures of muscle strength show the decline early.

- **Vital capacity (VC):** the largest volume of air a person can breathe out after a full breath in, recorded in litres or millilitres per kilogram. Forced vital capacity (FVC) uses a forceful breath out. For GBS, the European Academy of Neurology and Peripheral Nerve Society guideline advises checking FVC three to six times daily, according to how severe the illness is. It states that a fall of more than 30% in 24 hours likely means immediate transfer to intensive care, and that planned (elective) ventilation should be considered once FVC reaches 20 mL/kg or less (van Doorn et al., 2023).
- **Negative inspiratory force (NIF):** also called maximum inspiratory pressure, the strongest pull the person can make when breathing in against a closed valve. The "20/30/40 rule" flags a risk of respiratory failure when VC is below 20 mL/kg, maximum inspiratory pressure is below 30 cm H_2O or maximum expiratory pressure is below 40 cm H_2O (Leonhard et al., 2019).
- **Single-breath count:** the patient counts aloud on one breath. A count below 20 is a useful bedside sign that intensive care may be needed (van Doorn et al., 2023).

Oxygen saturation is a late sign. Because the lungs exchange gas normally, saturation can stay normal until the muscles are close to failing, and respiratory failure can occur without breathlessness (Leonhard et al., 2019). A falling VC is the signal to escalate, even when saturation is normal. In MG, the same measures are used, with thresholds set by the treating team.

CLINICAL JUDGMENT

Weak, Then Weaker

Names and details are fictional; this is a composite story.

Amira Haddad, 58, has had MG for 6 years. She is admitted to a medical unit with pneumonia and started on antibiotics. On day 2, the nurse notices that she leaves half her lunch and holds her chin up with her hand to speak.

- **Recognize cues:** Her voice is nasal and fades during conversation. She coughs while swallowing water and pockets pills in her cheek. Her eyelids droop more than this morning. She counts only to 14 on one breath. Her FVC is 1.6 L, down from 2.3 L at 0800. Her oxygen saturation is 95%. Her 1200 pyridostigmine was given on time.
- **Analyze cues:** Infection is a known trigger for MG. Her swallowing, voice and breathing measures are worsening together, which points to bulbar and respiratory muscle weakness. A normal saturation does not rule out a problem.
- **Prioritize hypotheses:** Impending myasthenic crisis, with a risk of aspiration and respiratory failure, comes first. A cholinergic reaction is less likely, but the team must judge it.
- **Generate solutions:** Stop food and fluids by mouth; sit her upright; have suction ready; escalate now; check new medication orders against the list of drugs that can worsen MG.
- **Take action:** The nurse makes her NPO, sits her upright and calls the rapid response team per policy. Using SBAR (situation, background, assessment, recommendation; Chapter 6), the nurse reports the trend in FVC, the single-breath count and swallowing to the RN in charge and the physician (Chapter 6). The nurse asks the pharmacist to review her antibiotic, which is a macrolide. The nurse stays with her and explains each step.
- **Evaluate outcomes:** The critical care outreach team transfers her to a step-down unit. Plasma exchange is started, and her antibiotic is changed. Two days later her FVC is 2.4 L, her voice is clear and she passes a swallowing assessment.

32.6 Amyotrophic Lateral Sclerosis and Living With Progressive Neurologic Disease

Some neurologic diseases cannot be cured, and they progress. Nursing care then aims to keep the person as independent, comfortable and in control as possible, and to support the family who share the work of care.

Amyotrophic Lateral Sclerosis

Amyotrophic lateral sclerosis (ALS) is a progressive disease in which the motor nerve cells of the brain and spinal cord degenerate (Shoesmith et al., 2020). Loss of upper motor neurons, in the brain, causes stiffness and spasticity. Loss of lower motor neurons, in the brainstem and spinal cord, causes weakness, muscle wasting and twitching called fasciculations. In about 70% of people, ALS starts in a limb, for example with a weak hand or a dropped foot. In about 25%, it starts in the bulbar muscles, with slurred speech or trouble swallowing (Shoesmith et al., 2020). Sensation, bladder control and, often, thinking are spared at first. About half of people with ALS develop detectable changes in thinking or behaviour linked to the frontal and temporal lobes, and in about 20% these changes reach the level of dementia (Shoesmith et al., 2020; Figure 32.6).

ALS in Canada. ALS Canada (2025) reports that nearly 4,000 Canadians are living with ALS, and that each year about 1,000 Canadians die of it and a similar number are diagnosed. More than 90% of people diagnosed have no family history of the disease, and about 80% of people with ALS die 2 to 5 years after diagnosis (ALS Canada, 2025), usually from respiratory failure (Shoesmith et al., 2020).

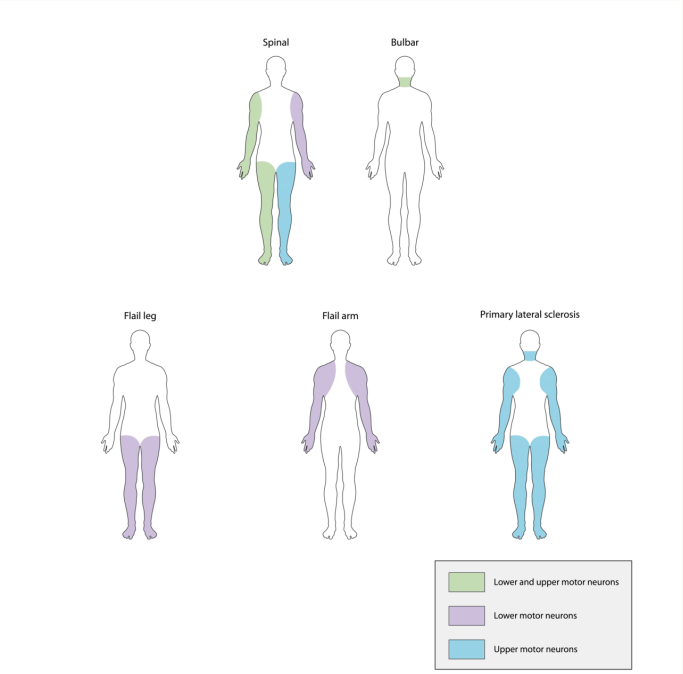

Figure 32.6 Distribution of upper motor neuron (UMN) and lower motor neuron (LMN) involvement across classical spinal-onset, bulbar-onset and variant subtypes of amyotrophic lateral sclerosis (ALS). (credit: "ALS subtypes UMN LMN distribution" by PaulWicks/Wikimedia Commons, CC BY-SA 4.0)

Care. The Canadian best practice recommendations advise regular follow-up in a multidisciplinary ALS clinic together with primary care. Such clinics have been linked with longer survival and fewer hospital admissions (Shoesmith et al., 2020). Two medications are approved in Canada. Riluzole, approved in 2000, gives a modest survival benefit, and liver enzymes and blood counts are monitored. Edaravone, approved in October 2018, is rated "probably effective" only in a select group of patients (Shoesmith et al., 2020).

Breathing and feeding decisions. As breathing muscles weaken, **noninvasive ventilation (NIV)**, breathing support through a mask, eases breathlessness and helps sleep. The recommendations suggest starting NIV in a person without symptoms when FVC falls to 65% of predicted or other criteria are met, and starting it within 4 weeks of meeting criteria (Shoesmith et al., 2020). A cough-assist device is considered when the cough becomes weak (Chapter 15). As swallowing fails and weight drops, a feeding tube may be offered, with no more than 4 weeks' delay after criteria are met (Shoesmith et al., 2020; section 24.3). These are personal choices that depend on the person's goals, and they are best discussed early, before an emergency.

Communication. When speech fails, communication tools range from letter and picture boards to speech-generating devices and eye-gaze computers (Shoesmith et al., 2020). Early referral to a speech-language pathologist lets the person bank their voice or learn a device while they still have the strength to do so.

Living Well With Progressive Disease

Advance care planning. Advance care planning is the ongoing process of reflecting on values and wishes for future care, sharing them with family and the care team, and choosing a substitute decision-maker. The ALS recommendations favour bringing palliative

care in early and adjusting it as needs change, and starting advance care planning when the person is ready (Shoesmith et al., 2020). The same approach suits advanced MS, PD and other progressive diseases. The nurse invites the conversation, listens and documents wishes (Chapter 10). Some people with ALS and other serious illnesses ask about medical assistance in dying (MAID). The nurse responds respectfully and follows Chapter 10 and employer policy.

Caregivers. A **caregiver** is a family member or friend who provides unpaid care and support. Caring for a person with ALS affects the caregiver's own quality of life, and strain rises with advanced disability and changes in thinking (Shoesmith et al., 2020). The nurse asks how the caregiver is coping, includes them in planning, teaches skills such as transfers and feeding, and links them with respite.

Home, equipment and access. People with progressive disease need mobility aids, home changes, home care and help with costs, and their needs grow over time. The nurse refers early to occupational therapy, social work and home care, and treats accessibility as a right (Chapter 2). People in rural, remote and northern communities may need to travel far to specialty clinics. Virtual visits, outreach clinics and local primary care partners help. Care is offered in French and other languages through interpreters, and care with First Nations, Inuit and Métis people involves community health services and family as the person wishes (Chapter 2).

Hospital stays. When a person with ALS or another progressive disease is admitted, the nurse keeps the person's own NIV machine, communication device and routines in place wherever policy allows. The nurse asks the person and caregiver how care is done at home, since they often know the safest way to transfer, position and feed. Discharge planning starts at admission, because needs may have changed during the stay.

Peer support. National organizations, such as MS Canada, Parkinson Canada and ALS Canada, offer information, equipment programs and peer support. The nurse shares these resources at diagnosis and again at each transition.

Table 32.4 summarizes nursing points for the medicines named in sections 32.3 to 32.6.

Table 32.4 Medicines for chronic neurologic disorders (Canadian monographs and guidelines)

Drug or class	Canadian examples	Used for	Nursing points
Levodopa with carbidopa	Levodopa-carbidopa tablets, including controlled release; intestinal gel	Motor symptoms of Parkinson disease	Give at the person's own clock times; never stop suddenly; watch for low blood pressure on standing, sudden sleep, hallucinations and dyskinesia; ask the pharmacist about iron and high-protein meals
Dopamine blockers (to avoid in Parkinson disease)	Metoclopramide; phenothiazine and butyrophenone antipsychotics; risperidone	Nausea, agitation or psychosis in other patients	Question the order; ask the prescriber or pharmacist for an alternative; for psychosis in Parkinson disease, the guideline names quetiapine or clozapine with monitoring
Disease-modifying therapies for MS	Oral: fingolimod, siponimod, ozanimod, cladribine. Infusion or injection: ocrelizumab, ofatumumab, alemtuzumab, natalizumab	Reducing relapses and slowing MS	Record the last dose; report fever and infection; for natalizumab, observe during and 1 hour after infusion and teach PML warning signs
Corticosteroids	Prednisone; methylprednisolone	MS relapses; MG	Avoid long-term use when possible; in MG, report new weakness after starting
Cholinesterase inhibitor	Pyridostigmine (regular and slow-release tablets)	Symptoms of MG	Give on time; swallow whole, do not crush; watch for excess saliva, cramps and diarrhea; report any worsening weakness
Immune therapies	IVIG; plasma exchange (a procedure)	Severe MG or crisis; GBS in patients who cannot walk unaided	Given per order and employer policy; monitor vital signs, breathing and reactions
ALS medications	Riluzole; edaravone	Slowing ALS	Riluzole: monitor liver enzymes and blood counts as ordered; edaravone: benefit limited to selected patients

SCOPE IN PRACTICE

Neurologic Care and Who Does What

The College of Nurses of Ontario (CNO) Scope of Practice standard asks every nurse to consider **authority**, **competence** and **context** before taking on an activity (section 1.3).

- **Spinal precautions:** Log rolling a patient with a spinal injury is a team task; trained nurses take part, and no nurse moves the patient alone (section 32.2).
- **Autonomic dysreflexia:** Any nurse who sees the signs starts the first actions at once and calls for help (section 32.2). No nurse waits for someone else.
- **Breathing in MG and GBS:** RNs and RPNs both measure vital capacity or single-breath counts when the employer authorizes it and they are trained. Any nurse who sees a falling trend escalates at once. The RPN consults the RN as the patient's needs change; depending on employer policy, the RN may take over care of a patient who is becoming unstable.
- **IVIG and plasma exchange:** IVIG is a blood product. Employer policy sets who may give it, and plasma exchange is often done in specialized units. These limits come from employer policy, based on context and competence, not from a CNO rule.
- **Medications on time:** Every nurse who gives medications to a person with PD gives them at the person's own times and questions an order for a dopamine blocker.
- **Advance care planning:** Both RNs and RPNs listen to and document wishes within their competence.

Employer policy and the province or territory matter. In other provinces, practical nurses (licensed practical nurses in many provinces) follow their own regulator's standards.

Chapter 32 Summary

32.1 Traumatic Brain Injury and Concussion

- More than 20,000 people in Canada are hospitalized for TBI each year; falls are the leading cause of head injury hospitalization, and rates are highest among people over 85.
- Primary injury happens at impact; nurses work to prevent secondary injury by protecting oxygenation, blood pressure, temperature and positioning, and by reporting neurologic decline at once.
- Concussion is a clinical diagnosis. After about 24 to 48 hours of relative rest, people return to activity gradually; most adults recover within about a month, and those with symptoms beyond a month are considered for interdisciplinary care.
- Warning signs such as repeated vomiting, a worsening headache or increasing drowsiness need emergency care.
- An epidural hematoma can follow a lucid interval; a chronic subdural hematoma can appear weeks after a minor fall in an older adult as new confusion. Older adults taking anticoagulants need prompt assessment after a head injury.
- During post-traumatic amnesia, a calm, low-stimulation setting with consistent staff is preferred to restraints and sedation.

32.2 Spinal Cord Injury

- About 86,000 people in Canada live with SCI; falls are the most common cause of traumatic SCI, and degenerative disease the most common cause of non-traumatic SCI.
- The neurologic level and completeness (sacral sparing on the ISNCSCI examination) predict function; cervical injuries cause tetraplegia and threaten breathing.
- Early care includes spinal motion restriction and log rolling, close respiratory monitoring with secretion clearance and assisted cough, and recognition of neurogenic shock and VTE risk.
- Autonomic dysreflexia, usually with injuries at T6 or above, is an emergency: sit the person up, loosen clothing, check the bladder, then the bowel and skin, monitor blood pressure every 2 to 5 minutes and call for help early.
- Ongoing care covers bladder, bowel, skin, temperature, spasticity, sexuality and mood, with rehabilitation aimed at living in the community.

32.3 Multiple Sclerosis

- MS is a chronic autoimmune disease in which the immune system damages myelin in the optic nerves, brain and spinal cord.
- Most people are first diagnosed with relapsing-remitting MS; a relapse lasts at least 24 to 48 hours with no outside cause.
- Heat, fever and infection can cause a pseudo-relapse, so the nurse looks for infection before assuming a relapse.
- In 2021–2022, about 290 per 100,000 Canadian adults lived with MS, and about 7 in 10 were women.
- Disease-modifying therapies act on the immune system; nurses report infection and teach warning signs such as those of PML with natalizumab.

32.4 Parkinson Disease

- PD causes tremor, rigidity, slow movement and poor balance, plus non-motor symptoms such as constipation, low mood, sleep problems and orthostatic hypotension.
- Levodopa-carbidopa is the most effective treatment for motor symptoms; it must be given at the person's own clock times, every time.
- Stopping PD medication suddenly can cause a dangerous reaction with rigidity, fever and confusion; NPO plans are made ahead with the team.
- Dopamine blockers, such as metoclopramide and many antipsychotics, are avoided; the nurse questions these orders.

32.5 Myasthenia Gravis and Guillain–Barré Syndrome

- MG causes weakness that worsens with use; myasthenic crisis is weakness that needs ventilatory support.
- Infection and some drugs, such as fluoroquinolones, macrolides and magnesium, can worsen MG; the nurse checks new orders.
- GBS often follows an infection and causes tingling, rising weakness, lost reflexes, pain and autonomic swings.
- In both disorders, a falling vital capacity, weak cough or swallowing trouble means early escalation; oxygen saturation falls late.
- IVIG and plasma exchange are used in both disorders; corticosteroids are not recommended for GBS.

32.6 Amyotrophic Lateral Sclerosis and Living With Progressive Neurologic Disease

- ALS destroys motor nerve cells, causing weakness, wasting and, eventually, respiratory failure; nearly 4,000 Canadians live with it.
- Multidisciplinary ALS clinics, riluzole and edaravone, NIV, feeding tubes and communication devices support quality of life.
- Advance care planning and early palliative care are best started when the person is ready, before a crisis (Chapter 10).
- Caregivers need assessment, teaching and respite, and accessible care reaches rural, francophone and Indigenous communities.

Key Terms (49)

advance care planning: The ongoing process of reflecting on values and wishes for future care, sharing them with family and the care team, and choosing a substitute decision-maker.

amyotrophic lateral sclerosis (ALS): A progressive disease in which the motor nerve cells of the brain and spinal cord degenerate, causing weakness, muscle wasting and, eventually, respiratory failure.

areflexia: Absence of deep tendon reflexes.

ascending paralysis: Weakness that starts in the legs and spreads upward to the arms and the muscles of breathing, swallowing and the face.

autonomic dysfunction: Damage to the nerves that control heart rate, blood pressure, bowel and bladder, causing swings in vital signs and other problems.

autonomic dysreflexia: A sudden, dangerous rise in blood pressure, triggered by a stimulus below a spinal cord injury, usually at T6 or above.

bradykinesia: Slowness of movement, seen as small steps, a soft voice and small handwriting.

caregiver: A family member or friend who provides unpaid care and support to a person with an illness or disability.

cholinergic crisis: Severe weakness, with excess secretions and other cholinergic effects, caused by too much cholinesterase inhibitor.

complete injury: A spinal cord injury with no sensation or movement preserved in the lowest sacral segments (S4–S5).

concussion: A type of mild traumatic brain injury from a force that moves the brain within the skull, causing neurologic changes that usually resolve on their own, with normal standard imaging.

demyelination: Damage to or loss of the myelin covering of nerve fibres, which slows or blocks nerve signals.

diffuse axonal injury: Widespread stretching and tearing of nerve fibres caused by rapid acceleration and deceleration of the brain.

disease-modifying therapy (DMT): A long-term medication that changes the course of MS by acting on the immune system, reducing relapses and slowing disability.

dyskinesia: Involuntary writhing or jerking movements, often a side effect of long-term levodopa treatment.

epidural hematoma: A collection of blood between the skull and the dura.

Guillain–Barré syndrome (GBS): An acute immune attack on the peripheral nerves, often after an infection, causing rapidly rising weakness and loss of reflexes.

incomplete injury: A spinal cord injury with some sensation or voluntary movement preserved in the lowest sacral segments.

levodopa: A medication that the brain converts to dopamine; combined with carbidopa, it is the most effective treatment for the motor symptoms of Parkinson disease.

log roll: Turning a patient so that the head, shoulders, trunk and hips move together as one unit and the spine does not twist.

lucid interval: A period after a head injury when the person wakes and seems well before deteriorating, typical of an epidural hematoma.

multiple sclerosis (MS): A chronic autoimmune disease in which the immune system damages myelin in the optic nerves, brain and spinal cord.

myasthenia gravis (MG): An autoimmune disease in which antibodies block signals at the neuromuscular junction, causing weakness that worsens with use and improves with rest.

myasthenic crisis: MG weakness that worsens until the person needs intubation, or noninvasive ventilation to prevent intubation.

myelin: The fatty covering that insulates nerve fibres and lets signals travel quickly.

neurogenic shock: Low blood pressure with a slow heart rate, without another cause, after a cervical or high thoracic spinal cord injury, from sudden loss of sympathetic nerve output.

neuromuscular junction: The site where a motor nerve passes its signal to a muscle fibre.

noninvasive ventilation (NIV): Breathing support given through a mask rather than a tube in the airway.

orthostatic hypotension: A drop in blood pressure on standing that causes dizziness, light-headedness or fainting.

paraplegia: Weakness or paralysis of the trunk, legs or both, sparing the arms, from an injury below the cervical cord.

Parkinson disease (PD): A chronic, progressive neurologic disease marked by tremor, rigidity, slow movement and poor balance, with many non-motor symptoms.

post-traumatic amnesia: A stage of recovery after TBI in which awareness is poor and fluctuates, the person is disoriented and new events are not reliably remembered.

primary brain injury: Damage that occurs at the moment of impact or sudden acceleration and deceleration.

progressive multifocal leukoencephalopathy (PML): A rare, serious brain infection caused by the JC virus; a risk with some immune-modifying drugs such as natalizumab.

pseudo-relapse: A short-lived return or worsening of earlier MS symptoms caused by heat, fever, infection or fatigue, without new inflammation.

ptosis: Drooping of the upper eyelid.

relapse: In MS, new symptoms or a clear worsening of existing ones lasting at least 24 to 48 hours when no outside factor such as infection or heat explains it.

resting tremor: Rhythmic shaking, often of one hand, that is present when the limb is at rest.

rigidity: Stiffness of the muscles felt when another person moves the limb.

secondary brain injury: Further brain damage in the hours and days after injury from low oxygen, poor blood flow, swelling and harmful chemical changes.

spasticity: Increased muscle tone with involuntary spasms and overactive reflexes after damage to the brain or spinal cord.

spinal cord injury (SCI): Damage to the spinal cord that interrupts messages between the brain and the body below the injury.

spinal motion restriction: Keeping the spine as still as possible, for example with a cervical collar and careful movement, when a spine injury is possible.

spinal shock: A temporary state, beginning immediately after a spinal cord injury, in which spinal reflexes are lost below the injury.

subdural hematoma: A collection of blood between the dura and the surface of the brain; it may be acute or chronic.

tetraplegia: Weakness or paralysis of the arms, trunk and legs from an injury to the cervical spinal cord.

traumatic brain injury (TBI): Damage to the brain from an outside force, such as a blow to the head or a jolt that moves the brain quickly inside the skull.

vital capacity: The largest volume of air a person can breathe out after a full breath in; a bedside measure of breathing muscle strength.

wearing off: The return of Parkinson symptoms before the next dose of medication is due.

Licensure Review & Clinical Judgment Questions (40)

Questions tagged **[Core]** apply to all nursing students (NCLEX-RN, REx-PN, and CPNRE). Questions tagged **[RN]** draw on *Going Deeper* content.

Case: Amara Osei (Questions 1–4): Amara Osei, 32, has a complete T4 spinal cord injury from a car crash five months ago and is on a rehabilitation unit in Ontario with an indwelling urinary catheter. Her usual blood pressure is 98/62 mm Hg. While lying flat in bed, she calls the RPN and says she has a pounding headache. Her face and neck are flushed and sweaty, the skin on her legs is cool with goosebumps, her blood pressure is 188/104 mm Hg and her heart rate is 52 beats/min.

1. [CORE] Which action should the RPN take first?

a. Lower the head of the bed and raise her legs to improve blood flow to her brain.

b. Give the analgesic she has ordered as needed for headache and recheck her in one hour.

c. Sit her up at 90 degrees and lower her legs over the side of the bed or into a dependent position.

d. Leave the room to call the physician, and plan to recheck her vital signs once orders are received.

Answer: c — Ms. Osei has the signs of autonomic dysreflexia: an injury above T6, pounding headache, flushing and sweating above the injury, goosebumps below, and a blood pressure far above her baseline with a slow heart rate (section 32.2, Autonomic Dysreflexia). Sitting her upright and lowering her legs helps lower the pressure at once. Option a raises the pressure further and is the opposite of what is needed. Option b treats the headache but ignores the dangerous blood pressure and its cause. Option d delays action; any nurse who recognizes AD starts the first steps at once and calls for help while staying with the patient.

2. [CORE] Ms. Osei is now sitting upright and her clothing is loosened. Her blood pressure is 182/100 mm Hg. Which action should the RPN take next?

a. Check the catheter and tubing for kinks or clamps and look at whether urine is draining into the bag.

b. Perform a digital rectal check for stool before looking at the bladder, because constipation is the most common cause.

c. Ask her to rate her headache on a 0 to 10 scale and document it before taking any other action.

d. Turn her onto her side to check her sacrum and heels for pressure areas that may be the trigger.

Answer: a — A full bladder, often from a blocked or kinked catheter, is the most common trigger of AD, so the bladder is checked before the bowel and skin (section 32.2, Autonomic Dysreflexia; Clinical Safety box). Option b reverses the order; the bowel is checked after the bladder, and constipation is not the most common cause. Option c delays the search for the cause. Option d checks the skin before the more likely causes and moves her out of the upright position.

3. [CORE] The RPN finds a kink in the catheter tubing and straightens it. Urine begins to drain. Which action should the RPN take at the same time?

a. Document the episode in detail at the end of the shift, because the cause has now been found and removed.

b. Notify the RN and the physician or NP, and keep checking her blood pressure every 2 to 5 minutes.

c. Clamp the catheter after 500 mL so that the bladder does not empty too quickly.

d. Lay her flat in bed as soon as urine is draining so that she can rest comfortably after the episode.

Answer: b — The RPN reports AD early and keeps monitoring the blood pressure every 2 to 5 minutes until it settles, calling the emergency response if it does not fall (section 32.2, Autonomic Dysreflexia). Option a delays reporting; the team needs to know now in case the pressure stays high and medicine is needed. Option c is not part of the first actions taught in this chapter and could leave the trigger in place. Option d is premature; she stays upright until the pressure is back to her usual level.

4. [CORE] Ms. Osei's blood pressure returns to 104/66 mm Hg. Which teaching point is most important for her before discharge?

a. "Lying flat during an episode is the safest way to bring your blood pressure down quickly."

b. "A blood pressure of 130 over 80 is normal for adults, so you only need to get help if it goes above 160."

c. "This happens only in the first few months after an injury, so you will not need to watch for it once you are home."

d. "Carry a wallet card with the warning signs, first steps and your usual blood pressure, and show it to staff."

Answer: d — A wallet card helps her and health care staff, who may not know about AD, act quickly (section 32.2, Autonomic Dysreflexia). Option a is wrong; she should sit up. Option b is dangerous; her usual pressure is about 98/62 mm Hg, and for people like her a systolic reading above 130 mm Hg can already be a sign of AD. Option c is wrong; episodes are not limited to the first months after injury (almost everyone at risk has an episode within the first year), so she keeps her prevention routines and her wallet card at home.

5. [CORE] An adult is seen in a clinic two days after a concussion from a fall while skating. Which statement by the patient shows understanding of the plan for activity?

a. "I will stay in bed in a dark, quiet room until every one of my symptoms is completely gone, however long it takes."

b. "I can go back to playing hockey tomorrow if my headache is gone by the morning."

c. "I'll increase my activity a little at a time, and slow down if my symptoms stay worse for more than a day."

d. "I should avoid all walking and reading for at least two weeks so my brain can fully heal."

Answer: c — After about 24 to 48 hours of relative rest, the Living Concussion Guidelines encourage a gradual return to activity, slowing the pace if symptoms worsen for more than about 24 hours (section 32.1, Concussion and Mild TBI). Option a is wrong; complete bed rest for more than three days should be avoided. Option b is unsafe; activities with a high risk of another concussion should be avoided, particularly in the first 7 to 10 days. Option d prolongs rest beyond what the guideline recommends; light activity such as walking is encouraged.

6. [CORE] The nurse is teaching a patient and a support person before discharge after a concussion. Which findings should prompt them to go to the emergency department or call 9-1-1? Select all that apply.

a. Vomiting more than twice

b. A headache that keeps getting worse

c. Feeling more tired than usual in the evening

d. Fluid or blood coming from the nose or ear

e. Being very hard to wake up

f. Mild trouble concentrating while reading

Answer: a, b, d, e — Vomiting more than twice, a worsening headache, fluid or blood from the ear or nose, and being hard to wake are warning signs that call for emergency care (section 32.1, Patient Education: After a Concussion). Options c and f are common, expected symptoms of concussion that usually improve with a gradual return to activity; they need follow-up if they persist, not emergency care.

7. [CORE] An 82-year-old woman who takes an anticoagulant for atrial fibrillation tripped in her kitchen and struck her head an hour ago. She is alert, oriented and says she feels fine. Which action by the nurse in the community clinic is most appropriate?

a. Arrange urgent assessment by a physician or NP and report her anticoagulant use.

b. Reassure her that she does not need assessment because she is alert and did not lose consciousness.

c. Tell her to hold her next anticoagulant dose and to call the clinic tomorrow if she has a headache.

d. Apply the Canadian CT Head Rule to decide whether she needs a CT scan and tell her the result.

Answer: a — The Canadian CT Head Rule does not apply to people taking anticoagulants, who need extra consideration, and age over 65 is a risk factor; she needs prompt assessment even though she seems well (section 32.1, Lifespan Considerations: Head Injury in Older Adults). Option b misses that bleeding may develop later and that older adults often have few early signs. Option c delays assessment and changes a medicine without an order. Option d is outside the nurse's role, and the rule does not apply to people taking anticoagulants.

8. [CORE] A patient admitted after a fall with a skull fracture was talking and oriented two hours ago. Now he is harder to wake and answers with confused words. Which action should the RPN take first?

a. Document the change and plan to repeat the neurologic check at the next scheduled time.

b. Give the ordered analgesic, because pain may be making him drowsy, restless and less cooperative with checks.

c. Report the change to the RN at once and call the rapid response team if criteria are met.

d. Encourage him to sleep, because rest is the main treatment for a brain injury.

Answer: c — A falling level of consciousness after a head injury may mean an expanding hematoma, such as an epidural hematoma after a lucid interval, and needs immediate escalation (section 32.1, Moderate and Severe TBI; Chapter 6). Option a delays action for a possibly life-threatening change. Option b may hide further decline and does not address its cause. Option d ignores a sign of deterioration.

9. [CORE] An 84-year-old man is brought to the clinic by his daughter because he has become forgetful and unsteady over the past three weeks. She mentions that he slipped on his front step about a month ago but "didn't hit hard." Which response by the nurse is most appropriate?

a. Tell the daughter that these changes are typical of normal aging and suggest a memory clinic referral next year.

b. Report the new confusion and recent fall to the physician or NP as a possible chronic subdural hematoma.

c. Suggest that the family increase his fluid intake and recheck his memory in two weeks.

d. Advise the daughter that a minor fall a month ago is too long ago to explain his symptoms.

Answer: b — A chronic subdural hematoma can appear days to weeks after a low-energy fall in an older adult, and cognitive impairment is its main symptom, so it can be mistaken for dementia (section 32.1, Moderate and Severe TBI). Option a assumes aging and delays assessment. Option c delays assessment of a possibly serious cause. Option d is wrong; the interval from injury can be up to two months.

10. [CORE] A patient with a moderate TBI is receiving oxygen. Which finding should the nurse act on first to prevent secondary brain injury?

a. Temperature 37.2 °C

b. Head of the bed at 30 degrees

c. Oxygen saturation 89%

d. Systolic blood pressure 128 mm Hg

Answer: c — Low oxygen causes secondary brain injury; the ENLS protocol recommends keeping SpO_2 at 94% or higher (section 32.1, Moderate and Severe TBI). Option a is a normal temperature. Option b is the recommended head-of-bed position. Option d is above the recommended minimum systolic pressure.

11. [CORE] A patient recovering from a severe TBI is in post-traumatic amnesia. He is restless, pulls at his blanket and tries to climb out of bed. Which nursing approach is most appropriate?

a. Keep the room quiet, limit visitors, use consistent staff and give simple orienting cues.

b. Ask for an order for a benzodiazepine to keep him calm through the night shift.

c. Apply bilateral wrist restraints and recheck his behaviour every four hours.

d. Turn on the television and invite several family members to visit at once to stimulate him.

Answer: a — The Canadian rehabilitation guideline recommends a secure, supervised, low-stimulation environment with consistent staff and orienting information during PTA (section 32.1, Moderate and Severe TBI). Options b and c run against the guideline, which advises minimizing sedating medicines and restraints because they may slow emergence from PTA. Option d adds stimulation that the injured brain may not tolerate.

12. [CORE] Six weeks after a concussion, a 38-year-old office worker still has headaches and trouble concentrating and has not returned to work. Which action is most consistent with the Living Concussion Guidelines?

a. Advise her to stay in bed until the headaches stop, then return to full duties.

b. Tell her that symptoms lasting six weeks are no longer related to the concussion and need no follow-up.

c. Recommend that she resume her usual contact sports to test whether her brain has fully recovered.

d. Support referral to interdisciplinary concussion services and screen for depression and anxiety.

Answer: d — For symptoms lasting more than one month, the guideline recommends considering referral to interdisciplinary concussion services, and it recommends routine monitoring for depression and anxiety (section 32.1, Concussion and Mild TBI). Option a promotes prolonged bed rest, which should be avoided. Option b dismisses persisting symptoms, which affect at least one in six adults. Option c risks a second injury.

13. [CORE] A patient with a suspected cervical spine injury needs to be turned to check the skin on his back. Which action by the nurse is correct?

a. Ask the patient to grab the side rail and pull himself over while the nurse supports his head and neck.

b. Log roll him with enough trained staff, moving the head, shoulders and hips as one unit.

c. Remove the cervical collar first so that the skin under it can be checked during the turn.

d. Raise the head of the bed to 45 degrees before turning so that he can breathe more easily.

Answer: b — Until the spine is cleared, the patient is moved with a log roll so that the spine does not twist, using enough trained staff and following employer policy (section 32.2, Early Care). Option a twists the spine. Option c removes spinal motion restriction without an order. Option d bends the spine during the turn.

14. [CORE] A patient admitted yesterday with a C4 spinal cord injury has a weaker cough than this morning and is working harder to breathe. Which explanation best guides the nurse's response?

a. A C4 injury weakens the diaphragm and the muscles used to cough, so breathing can fail.

b. Weak coughing is expected after any SCI and does not need to be reported unless a fever also develops.

c. Lung problems after an SCI usually develop only after the first month, once the person starts rehabilitation.

d. The injury affects only the legs, so the breathing change is probably caused by anxiety.

Answer: a — The diaphragm is supplied mainly by C3 to C5, and the muscles for coughing by thoracic nerves, so a C4 injury puts breathing at serious risk; respiratory complications are common in acute SCI and need immediate reporting (section 32.2, Early Care). Option b delays escalation. Option c is wrong; respiratory complications are a major problem of the acute phase. Option d is wrong; a cervical injury causes tetraplegia and affects breathing.

15. [CORE] A patient with an acute C6 spinal cord injury has a blood pressure of 82/48 mm Hg and a heart rate of 46 beats/min. His skin is warm and dry, and there is no sign of bleeding. Which condition do these findings suggest?

a. Hypovolemic shock from internal bleeding

b. Autonomic dysreflexia

c. Spinal shock

d. Neurogenic shock

Answer: d — Neurogenic shock is low blood pressure with a slow heart rate, without another cause, after a cervical or high thoracic SCI (section 32.2, Early Care). Option a usually causes a fast heart rate. Option b causes high blood pressure. Option c is a temporary loss of reflexes below the injury, not a circulation problem.

16. [CORE] A man with paraplegia from an SCI two years ago tells the home care nurse that his leg spasms have suddenly become much worse over the past two days. What should the nurse assess for first?

a. Recovery of voluntary movement returning to his legs

b. A need for a firmer mattress to hold his legs still at night

c. A bladder infection or a new area of skin breakdown

d. Muscle strain from the exercises he does with his arms

Answer: c — When spasticity suddenly worsens for no clear reason, look for a problem below the injury; a bladder infection and a pressure area are common causes (section 32.2, Ongoing Care and Rehabilitation). Option a is unlikely to appear as a sudden worsening of spasms. Option b does not look for a cause. Option d does not explain a change in leg spasms below the injury.

17. [CORE] On a rehabilitation unit in Ontario, an RPN is assigned a patient with a cervical SCI who has had autonomic dysreflexia twice this week. Which statement best reflects CNO's approach to scope of practice?

a. RPNs may not care for patients with SCI, because CNO classifies every patient with an SCI as unstable and unpredictable.

b. She may provide care if she has the authority and competence, the context supports her, and she consults the RN as needs change.

c. The RPN must hand the patient over to an RN, but only after the patient's next episode of autonomic dysreflexia occurs.

d. The RPN may care for the patient only if the patient's condition is predictable and the risk of negative outcomes is low.

Answer: b — CNO's Scope of Practice standard uses authority, competence and context; employer policy and province or territory also matter, and the RPN consults the RN as the patient's needs change (section 1.3; section 32.2). Option a presents a patient classification as a CNO rule, which it is not. Option c waits for harm before getting support. Option d uses a retired three-factor framework that is no longer part of CNO's standard.

18. [RN] Two patients were admitted after head injuries. Patient A lost consciousness briefly, woke and talked normally, and two hours later became drowsy with a dilated right pupil. Patient B, 79 and taking an antiplatelet medicine, became confused and unsteady three weeks after a minor fall. Which interpretation is most accurate?

a. Patient A's picture fits a chronic subdural hematoma, and Patient B's picture fits an acute epidural hematoma.

b. Patient A's picture fits an epidural hematoma after a lucid interval, and Patient B's fits a chronic subdural hematoma.

c. Both patients most likely have concussions, which can be safely monitored at home with written discharge teaching.

d. Both patients most likely have diffuse axonal injury from acceleration and deceleration forces.

Answer: b — A brief loss of consciousness followed by a lucid interval and then decline is typical of an epidural hematoma; new confusion weeks after a low-energy fall in an older adult taking an antithrombotic medicine suggests a chronic subdural hematoma (section 32.1, Moderate and Severe TBI; Table 32.1). Option a reverses the two. Option c misses red flags that need urgent assessment. Option d does not fit; diffuse axonal injury follows acceleration and deceleration and alters consciousness from the moment of injury, not after a lucid interval or weeks later.

19. [RN] On day 1 after a C5 spinal cord injury, a patient has no reflexes in his legs, a blood pressure of 86/50 mm Hg and a heart rate of 50 beats/min. Which statement about this patient is accurate?

a. The absent reflexes show spinal shock, and the low blood pressure with a slow heart rate shows neurogenic shock.

b. The absent reflexes and the low blood pressure both show neurogenic shock, which is another name for spinal shock.

c. The slow heart rate shows that he is bleeding internally and needs a blood transfusion before any other care is given.

d. The absent reflexes prove that the injury is complete and that no recovery of function is possible.

Answer: a — Spinal shock is a temporary loss of reflexes below the injury; neurogenic shock is hypotension with bradycardia from loss of sympathetic tone after a cervical or high thoracic injury (section 32.2, Early Care). Option b confuses the two terms. Option c is wrong; bleeding usually causes a fast heart rate. Option d is wrong; completeness depends on sacral sparing on the ISNCSCI examination, not on reflexes during spinal shock.

20. [RN] An ISNCSCI examination shows a neurologic level of C6. The patient feels light touch and pinprick around the anus but cannot contract the anal sphincter and has no voluntary movement below C6. Which classification fits?

a. AIS A, complete, with no sacral sparing

b. AIS C, motor incomplete

c. AIS D, motor incomplete

d. AIS B, sensory incomplete

Answer: d — Preserved sensation in S4–S5 makes the injury incomplete; with no motor function below the level, it is AIS B, sensory incomplete (section 32.2, Going Deeper: Classifying Spinal Cord Injury). Option a requires no sacral sensation or movement. Options b and c require preserved motor function below the neurologic level.

Case: Daniel Kowalski (Questions 21–26): Daniel Kowalski, 44, was admitted to a medical unit 2 days ago with tingling in his feet and leg weakness that began 3 days after a bout of diarrhea 2 weeks earlier. He weighs 80 kg. The neurologist diagnosed Guillain–Barré syndrome, and IVIG was started yesterday. Today at 1400 he cannot lift his arms off the bed. His cough is weak, he speaks in short phrases and he counts to 14 on one breath. His FVC is 1.5 L, down from 2.4 L at 0800 and 3.6 L on admission. Over the past 4 hours his heart rate has varied from 52 to 128 beats/min and his blood pressure from 96/58 to 168/96 mm Hg. Oxygen saturation is 96% on room air, temperature 36.9 °C. His knee and ankle reflexes are absent. He says, "I can't get a proper breath. Am I going to die?"

21. [CORE] Which findings at 1400 should the nurse recognize as cues that need immediate follow-up? Select all that apply.

a. FVC of 1.5 L, down from 2.4 L at 0800

b. Weak cough and speaking in short phrases

c. Oxygen saturation of 96% on room air

d. Heart rate varying from 52 to 128 beats/min

e. Absent knee and ankle reflexes

f. New inability to lift his arms off the bed

Answer: a, b, d, f — A falling FVC, a weak cough with short phrases and weakness that has spread to his arms show that the weakness is rising toward the breathing muscles (a, b, f; section 32.5). Wide swings in heart rate show autonomic dysfunction, which can cause dangerous rhythms (d). A normal saturation is not reassuring in GBS, because it falls late (c; Going Deeper box). Absent reflexes are an expected finding in GBS and not a new change (e).

22. [CORE] Which explanation best links Mr. Kowalski's findings?

a. Anxiety about his diagnosis is causing him to breathe shallowly, which lowers his FVC and speeds up his heart rate.

b. A new chest infection from lying in bed is filling his lungs with secretions and making both his cough and his FVC worse.

c. GBS is spreading upward to his breathing muscles and has damaged the autonomic nerves that control heart rate and blood pressure.

d. IVIG started yesterday is causing an infusion reaction, which explains his blood pressure changes, breathing trouble and weakness.

Answer: c — GBS causes weakness that climbs from the legs to the arms and the muscles of breathing and swallowing, and autonomic involvement causes swings in heart rate and blood pressure (c; section 32.5). Anxiety does not explain a steady fall in FVC and spreading weakness (a). He has no fever, and his saturation is normal, so infection is less likely (b). An infusion reaction would not explain weakness that rises in the typical GBS pattern (d).

23. [RN] Which hypothesis should the nurse treat as the priority?

a. Impending respiratory failure, because his FVC has fallen by more than 30% today and is now about 19 mL/kg

b. Deep vein thrombosis, because he has been unable to move his legs for several days and is at high risk of a clot

c. Urinary retention from autonomic dysfunction, because a full bladder can raise blood pressure and heart rate

d. Severe anxiety, because he has asked whether he is going to die and needs reassurance and support right away

Answer: a — His FVC fell from 2.4 L to 1.5 L in 6 hours, a drop of more than 30%, and 1.5 L in an 80-kg man is about 19 mL/kg. The EAN/PNS guideline states that such a fall likely means transfer to intensive care and that elective ventilation should be considered at 20 mL/kg or less (a; Going Deeper box). Clot prevention, bladder checks and emotional support all matter, but breathing comes first (b, c, d).

24. [CORE] What should the nurse do first?

a. Give oxygen by nasal prongs, raise the head of the bed, and recheck his FVC and oxygen saturation again in 4 hours.

b. Ask the physician for an order for a sedative to relieve his anxiety and help him breathe more slowly and deeply.

c. Document the findings, increase his vital signs to every 2 hours and report them at the next scheduled handover.

d. Call the rapid response or critical care outreach team per policy and report the falling FVC and vital signs using SBAR.

Answer: d — A falling FVC, weak cough and autonomic swings are reasons to involve critical care now, so the nurse escalates at once with SBAR (d; section 32.5; Chapter 6). Oxygen does not treat weak muscles, and waiting 4 hours could allow respiratory failure (a). A sedative can depress breathing further (b). Documenting and waiting delays care for a deteriorating patient (c).

25. [CORE] While Mr. Kowalski waits for transfer and after he moves to the intensive care unit, which actions belong in his plan of care? Select all that apply.

a. Give VTE prophylaxis as ordered and check the fit of compression devices.

b. Reposition him on a schedule and inspect the skin over pressure points.

c. Explain each procedure to him and set up a call system that he can use.

d. Limit visits from his family so that he can rest and conserve his strength.

e. Offer thin fluids often to prevent dehydration while his cough is weak.

f. Ask him about pain and give analgesia as ordered, then reassess its effect.

Answer: a, b, c, f — Immobile patients with GBS need prevention of clots and pressure injuries (a, b; section 32.5; Chapters 19 and 35). He is fully awake and frightened, so explaining procedures and giving him a way to call for help are essential (c). Pain is common in GBS and must be assessed and treated (f). Family presence usually comforts rather than tires him, and limiting it is not part of the plan (d). Thin fluids are unsafe with a weak cough and possible swallowing weakness; his swallowing must be assessed first (e).

26. [CORE] Three days later, which finding best shows that his care is working?

a. He sleeps through most of the day and no longer asks questions about his illness or his treatment plan.

b. His FVC is stable at 2.0 to 2.1 L on three checks, his heart rate stays 72 to 90 beats/min and he uses the call system.

c. His oxygen saturation is 98% on 2 L of oxygen by nasal prongs, and his knee and ankle reflexes remain absent.

d. His blood pressure ranges from 100/60 to 170/98 mm Hg, and his weakness has spread to the muscles of his face.

Answer: b — A stable FVC on repeated checks, a steady heart rate and his ability to call for help show stable breathing, autonomic control and communication (b; section 32.5). Sleeping all day and no longer asking questions may signal fatigue, low mood or rising carbon dioxide, not improvement (a). Saturation on oxygen is a poor measure of muscle strength, and reflexes return late (c). Wide blood pressure swings and spreading weakness show the disease is still progressing (d).

27. [CORE] A woman with relapsing-remitting MS has had worse numbness and weakness in her legs since yesterday. Her temperature is 38.4 °C, and her urine is cloudy and foul-smelling. What is the best interpretation?

a. She is having a new relapse caused by fresh inflammation in her spinal cord, and high-dose corticosteroids should be started now.

b. Her MS has changed to the secondary progressive form, so her symptoms are expected to worsen steadily from now on.

c. Her disease-modifying therapy has stopped working, and she should ask her neurologist to change it to a different drug.

d. Her fever from a likely urinary tract infection may be causing a pseudo-relapse, so the infection should be reported and treated.

Answer: d — Fever and infection can bring back old symptoms without new inflammation, a pseudo-relapse that settles as the temperature returns to normal (d; section 32.3). A relapse is diagnosed only when no outside factor such as infection explains the change (a). One day of worse symptoms with fever does not show a change in disease course (b) or a failed DMT (c).

28. [CORE] A patient with MS receives natalizumab infusions. Which statement shows correct understanding of the teaching?

a. "My partner and I will report weakness on one side, clumsiness, vision changes or changes in my memory or personality."

b. "I can skip the hour of observation after my infusions now, because I have never had a reaction to the medicine before."

c. "If I have a cold sore, I should keep it to myself, because it is a minor problem that has nothing to do with this drug."

d. "This medicine has no serious infection risks, so I don't need regular check-ups with my prescriber while I am taking it."

Answer: a — The Canadian monograph warns of PML, which develops over days to weeks with one-sided weakness, clumsiness, vision changes and changes in thinking that the person may not notice, so partners are included (a; section 32.3). The monograph asks that patients be observed during each infusion and for an hour after it ends (b). The drug increases the risk of herpes infections of the brain and its coverings, so herpes symptoms are reported (c). Regular prescriber review is required (d).

29. [CORE] A patient with Parkinson disease is NPO after midnight for surgery at 1000. His home levodopa-carbidopa schedule is 0600, 0900, 1200, 1500 and 1800. What should the nurse do?

a. Hold all doses until after surgery, because nothing at all may be given by mouth while the patient is NPO for anesthesia.

b. Give the 0600 and 0900 doses together at 0600, so that he has enough medication on board to last through the surgery.

c. Contact the prescriber, anesthesia team and pharmacist before 0600 to plan how his doses will continue around surgery.

d. Ask his wife to give him his tablets from home at the usual times, because family members are not bound by NPO orders.

Answer: c — Missed or late doses can leave symptoms uncontrolled, and sudden withdrawal can cause a dangerous reaction, so the nurse plans with the team ahead of the first dose (c; section 32.4; Chapter 7). Simply holding doses is unsafe (a). Doubling doses is not ordered and may cause side effects (b). Asking family to give medications secretly bypasses the NPO plan and the care team (d).

30. [CORE] A patient with Parkinson disease says that he feels dizzy every morning when he gets out of bed. Which action is most appropriate?

a. Encourage him to get up quickly so that the dizziness passes before he walks to the bathroom.

b. Measure his blood pressure lying and standing and teach him to sit at the bedside before he stands.

c. Hold his morning levodopa-carbidopa dose until the dizziness has passed and his balance has returned.

d. Restrict his fluid intake in the evening so that he has fewer trips to the bathroom during the night.

Answer: b — Dizziness on rising suggests orthostatic hypotension, which is common in Parkinson disease and can be worsened by levodopa; the nurse measures orthostatic vital signs and teaches him to rise slowly (b; section 32.4). Getting up quickly increases the risk of falls (a). Holding levodopa worsens motor symptoms and is not the nurse's decision alone (c). Restricting fluids can worsen low blood pressure (d).

31. [CORE] Which findings in a patient with Parkinson disease are non-motor symptoms? Select all that apply.

a. Constipation

b. Loss of the sense of smell

c. Acting out dreams during sleep

d. Stiffness when the nurse moves the patient's arm

e. Low mood and loss of interest

f. Slowness of movement with small steps

Answer: a, b, c, e — Constipation, loss of smell, REM sleep behaviour disorder and depression or apathy are non-motor symptoms of Parkinson disease, and some may appear before the tremor (a, b, c, e; section 32.4). Rigidity (d) and bradykinesia (f) are motor signs.

32. [CORE] A patient with myasthenia gravis is starting pyridostigmine. Which teaching is accurate?

a. "If your weakness gets worse, take an extra tablet, because a larger dose of this medicine always improves your strength."

b. "Crush the slow-release tablets into applesauce if you have trouble swallowing them, so that the medicine works faster."

c. "Take your doses whenever you remember them, because the timing makes no difference to how well this medicine works."

d. "Take each dose on time, swallow the tablets whole, and report any worsening weakness instead of taking extra doses."

Answer: d — The monograph states that tablets are swallowed whole and not crushed, and that patients should not raise their dose without consulting the prescriber; too much can cause cholinergic weakness (d; section 32.5). Extra doses can cause a cholinergic crisis (a). Slow-release tablets must not be crushed (b). Timing matters so that strength peaks when it is needed, such as at meals (c).

33. [CORE] A patient with myasthenia gravis develops a urinary tract infection. The prescriber orders ciprofloxacin. What should the nurse do?

a. Contact the prescriber or pharmacist before giving it, because fluoroquinolones can worsen MG and a safer alternative may exist.

b. Give the first dose as ordered and then ask the patient to rate her weakness on a scale of 0 to 10 every morning for a week.

c. Give the medication with a double dose of pyridostigmine, so that any extra weakness from the antibiotic is prevented.

d. Hold the antibiotic until her MG symptoms are fully controlled, because infections do not affect MG and treatment can safely wait.

Answer: a — Fluoroquinolones are linked to MG worsening and are best avoided if a safer alternative exists, so the nurse questions the order before giving it (a; section 32.5). Giving it without question and only checking weakness daily may miss a crisis (b). Doubling pyridostigmine is not ordered and can cause a cholinergic crisis (c). Infection is itself a trigger for MG worsening, so it should not be left untreated (d).

34. [CORE] Which finding would the nurse expect when assessing a patient with early Guillain–Barré syndrome?

a. Weakness that started in the face and is now moving down toward the arms and legs

b. Brisk knee and ankle reflexes with a sustained beating of the foot when it is flexed upward

c. Tingling in the feet followed by leg weakness, with reduced or absent knee and ankle reflexes

d. Weakness on one side of the body only, with drooping of the face and slurred speech on the same side

Answer: c — GBS typically starts with tingling in the feet and hands, followed by weakness that rises from the legs, with reduced or absent reflexes (c; section 32.5). Weakness spreading downward from the face is not the typical pattern (a). Brisk reflexes suggest a problem in the brain or spinal cord, not the peripheral nerves (b). One-sided weakness with facial droop suggests a stroke (d; Chapter 31).

35. [CORE] A man with ALS says to the nurse, "My breathing is getting worse. I don't know whether I would want a breathing machine." What is the best response?

a. "That decision belongs to your neurologist, who will tell you which breathing support is best for you at your next visit."

b. "It helps to think about this early. What matters most to you as your illness changes, and who would you want involved?"

c. "Most people with ALS choose a breathing machine, so I would not worry about deciding this until you need it."

d. "Let's not talk about that today. Your breathing is still fine, and thinking about it will only make you feel anxious."

Answer: b — Advance care planning starts when the person is ready, and decisions about breathing support are best made early, before an emergency; the nurse explores his values and who he wants involved (b; section 32.6; Chapter 10). The decision is his, made with the team, not the neurologist's alone (a). Waiting until he needs it risks a crisis decision, and the claim about most people is unsupported (c). Closing the conversation ignores his concern (d).

36. [CORE] A patient with ALS is taking riluzole. Which tests should the nurse expect to be monitored?

a. Serum sodium and potassium levels

b. Thyroid-stimulating hormone level

c. Hemoglobin A1C and fasting glucose

d. Liver enzymes and blood counts

Answer: d — The Canadian ALS recommendations state that riluzole is generally well tolerated with monitoring of liver enzymes and blood counts (d; section 32.6; Table 32.4). The other tests are not the specific monitoring linked to riluzole (a, b, c).

37. [CORE] An RPN is caring for a patient with Guillain–Barré syndrome. At 1000, the patient's FVC is 2.1 L; at 1300, it is 1.5 L, and the patient has a weaker cough. What should the RPN do?

a. Report the change to the RN and the physician at once and stay with the patient, because a falling FVC needs urgent review.

b. Recheck the FVC at the next scheduled time, because a single low reading may simply be caused by poor effort from the patient.

c. Ask the patient to cough and deep breathe every hour and record the FVC result in the chart for the day shift to review.

d. Give oxygen by nasal prongs and wait for the RN to finish another patient's admission before reporting the change.

Answer: a — Any nurse who sees a deteriorating trend acts at once and escalates; the RPN consults the RN as the patient's needs change (a; Scope in Practice box; Chapter 6). Waiting for the next check delays care (b). Coughing exercises and documentation without reporting do not address the danger (c). Oxygen does not treat weak breathing muscles, and the report must not wait (d).

38. [CORE] On a medical unit, an RPN is asked to start an IVIG infusion for a patient with myasthenia gravis. What determines whether the RPN may do this?

a. A CNO rule that only RNs may give any intravenous medication or blood product to patients in hospital.

b. The patient's diagnosis, because MG is a chronic disease and RPNs may give any medication for chronic diseases.

c. The RPN's authority, competence and the context, including the employer's policy on who may give blood products.

d. The physician's order, because any nurse must give an ordered medication once a physician has written and signed the order.

Answer: c — CNO's Scope of Practice standard asks nurses to consider authority, competence and context, and employer policy sets who may give blood products such as IVIG (c; Scope in Practice box; section 1.3). No CNO rule limits all IV medications to RNs (a). The diagnosis alone does not decide who gives a medication (b). An order is needed, but the nurse must still have the authority and competence and must work in a suitable context (d).

39. [RN] A patient with myasthenia gravis, on day 2 of treatment for pneumonia, has a nasal voice, coughs when drinking, counts to 12 on one breath and has an FVC that has fallen from 2.2 L to 1.4 L since morning. Oxygen saturation is 96%. Which interpretation and action are best?

a. Cholinergic crisis from too much pyridostigmine is most likely, so the nurse gives an extra dose of pyridostigmine to see if strength improves.

b. Impending myasthenic crisis is likely, so the nurse makes the patient NPO, sits the patient upright and escalates for critical care review now.

c. The pneumonia is improving, because the oxygen saturation is normal, so the nurse continues the current plan and rechecks the FVC tomorrow morning.

d. The patient is tired from coughing, so the nurse plans rest periods, offers thin fluids slowly and reports the findings at handover.

Answer: b — Infection is a known trigger, and worsening swallowing, voice and breathing measures point to impending myasthenic crisis, which needs close monitoring and intensive care or step-down care if it progresses (b; section 32.5; Clinical Judgment box). Giving extra pyridostigmine is unsafe; the team judges whether cholinergic weakness is present (a). Normal saturation is a late sign and does not rule out muscle failure (c). Thin fluids are unsafe, and waiting for handover delays escalation (d).

40. [RN] A patient with Parkinson disease is on day 1 after abdominal surgery. Her levodopa-carbidopa is due at 1400; it is 1340. She is nauseated, and the postoperative order set includes metoclopramide intravenously as needed. What should the nurse do?

a. Give metoclopramide now and delay the levodopa-carbidopa until her nausea has settled, to make sure she keeps the tablets down.

b. Give metoclopramide now and give the levodopa-carbidopa on time, because metoclopramide speeds levodopa absorption and helps it work.

c. Hold both drugs until the surgeon's rounds tomorrow, because nausea after surgery usually resolves without any medication.

d. Give the levodopa-carbidopa on time and ask the prescriber for an antiemetic that does not block dopamine instead of metoclopramide.

Answer: d — Levodopa is time-critical, and metoclopramide blocks dopamine, may worsen disease control and should be given in Parkinson disease cautiously, if at all; the nurse gives the levodopa on time and asks for an alternative antiemetic (d; section 32.4). Delaying levodopa risks loss of motor control (a). Faster absorption does not offset metoclopramide's dopamine-blocking effect (b). Holding levodopa until tomorrow risks a dangerous withdrawal reaction and leaves nausea untreated (c).

IX Musculoskeletal, Integumentary & Sensory Care

UNIT CLINICAL SCOPE & INTEGRATION

Concludes with orthopedic trauma, fracture fixation, compartment syndrome and fat embolism surveillance, hip fracture standards and arthroplasty, osteoarthritis, rheumatoid arthritis, systemic lupus erythematosus, gout, Wounds Canada pressure injury and burn resuscitation care, and acute/chronic ophthalmic and otologic disorders.

Contents of UNIT IX

33 Musculoskeletal Trauma and Orthopedic Surgery

LEARNING OUTCOMES & COMPETENCY MAPPING

By the end of this chapter, you will be able to:

1. Describe how fractures happen and heal, and give first care and ongoing care for casts, splints, traction and external fixators.
2. Perform and interpret a neurovascular assessment of an injured limb and report changes at once.
3. Recognize compartment syndrome and fat embolism syndrome early and take the first nursing actions, using the CJMM.
4. Teach adults about osteoporosis, fracture risk and bone health, including how to take osteoporosis medicines safely.
5. Plan care for an older adult with a hip fracture from arrival to home, including delirium prevention, early mobilization and secondary fracture prevention.
6. Provide care before and after joint replacement, spine surgery and amputation, including teaching for home.
7. Move patients safely with appropriate equipment, and distinguish RN and RPN roles in orthopedic care using CNO's authority, competence and context.

How the outcomes map to the CNO entry-to-practice competencies

Outcome	RN competency role (CNO, 2019a)	RPN competency category (CNO, 2019b)
1, 2, 3, 5, 6	Clinician; Collaborator	Foundations of Practice; Collaborative Practice
4, 6	Educator; Advocate	Foundations of Practice
7	Professional; Coordinator	Legal Practice; Collaborative Practice

Introduction

A broken wrist after a slip on ice, a shattered shin bone after a dirt-bike crash, a hip that gives way in a kitchen at 2 a.m.: injuries to bones and joints are among the most common reasons adults come to hospital. Many heal well with a cast and time. Others need surgery, weeks of rehabilitation and careful nursing to prevent complications that can cost a limb or a life. Nurses on emergency, surgical, orthopedic and community teams are often the first to notice that something is wrong: pain that keeps climbing, a foot that is turning pale, a patient who is suddenly short of breath on the second day after a fracture.

This chapter is the book's home for musculoskeletal trauma and orthopedic surgery. Section 33.1 explains how bones break and heal, first care after injury, casts, splints, traction and external fixators, and the neurovascular assessment of an injured limb. Section 33.2 covers the serious complications that can follow, especially compartment syndrome and fat embolism syndrome. Section 33.3 turns to osteoporosis and bone health. The second half of the chapter covers hip fracture in older adults (33.4), joint replacement and spine surgery (33.5), amputation (33.6), and mobility and safe patient handling (33.7).

The chapter builds on earlier ones. Scope of practice for registered nurses (RNs) and registered practical nurses (RPNs) is taught in section 1.3, and the Clinical Judgment Measurement Model (CJMM) in section 1.4. In other provinces and territories, practical nurses (PNs) are often called licensed practical nurses (LPNs); this chapter uses "the nurse" unless the roles differ. Pain and multimodal analgesia are in Chapter 5, deterioration and SBAR (Situation, Background, Assessment, Recommendation) communication in Chapter 6, perioperative care in Chapter 7, delirium and falls in Chapter 8, and venous thromboembolism (VTE) in Chapter 19.

33.1 Fractures and Their Care

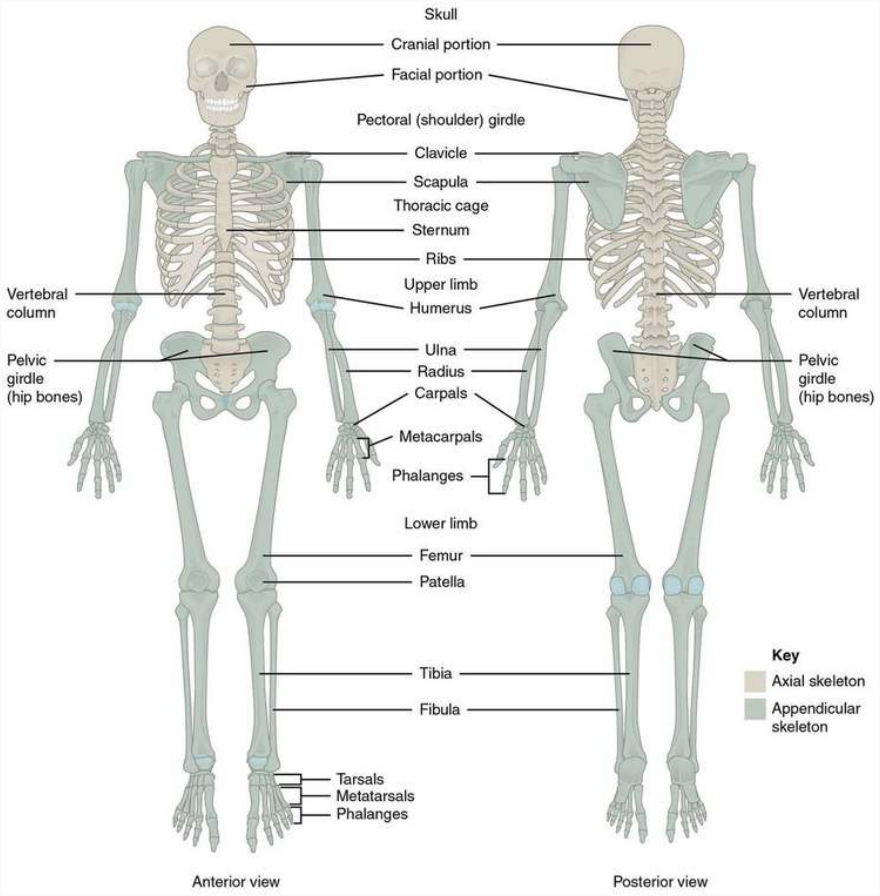

Figure 33.1 Anterior and posterior views of the adult human skeleton, showing the 80 bones of the axial skeleton (cranium, vertebral column, thoracic cage) and the 126 bones of the appendicular skeleton (pectoral girdle, pelvic girdle, upper and lower limbs). (credit: "Figure 7.2, Axial and Appendicular Skeleton" by J. Gordon Betts et al./OpenStax, Anatomy and Physiology 2e, CC BY-NC-SA 4.0)

How Bones Break and Heal

A **fracture** is a break in the continuity of a bone. Nurses describe fractures in plain terms because the words guide care and tell the team how serious the injury is (Figure 33.1).

- **Closed fracture:** the skin over the break is intact.
- **Open fracture:** the bone has broken through the skin, or a wound connects the outside world with the fracture. Bacteria can reach the bone, so infection is the main early concern (British Orthopaedic Association [BOA] & British Association of Plastic, Reconstructive and Aesthetic Surgeons [BAPRAS], 2017).
- **Complete and incomplete fractures:** a complete fracture goes all the way through the bone; an incomplete fracture breaks only part of it.
- **Displaced fracture:** the bone ends have moved out of their normal line.
- **Comminuted fracture:** the bone has broken into three or more pieces.
- **Pathologic fracture:** a break through bone already weakened by disease, such as a tumour that has spread to bone (Chapter 9).
- **Fragility fracture:** a break from low trauma, such as a fall from standing height, that would not normally break a healthy bone. A fragility fracture is a warning sign of osteoporosis (section 33.3) (Morin et al., 2023; Figure 33.12).

Treatment aims to put the pieces back in line and hold them there until they heal. **Reduction** is the return of the bone ends to their normal position, either by hand without an incision (closed reduction) or in surgery (open reduction). The bone is then held still with

a cast, splint, traction, an external fixator or internal fixation.

Most fractures heal through overlapping phases (Bahney et al., 2019). In the inflammatory phase, a blood clot forms within minutes, and inflammatory cells arrive to clear debris and send signals for repair. Next, new blood vessels grow into the area and repair cells move in from the bone's outer and inner linings. These cells form cartilage and then woven bone, called callus, that bridges the gap. Finally, during remodelling, bone-resorbing cells remove the temporary bone and replace it with strong, mature bone that slowly regains the bone's original shape. Inflammation is needed early but must settle for healing to go on (Bahney et al., 2019).

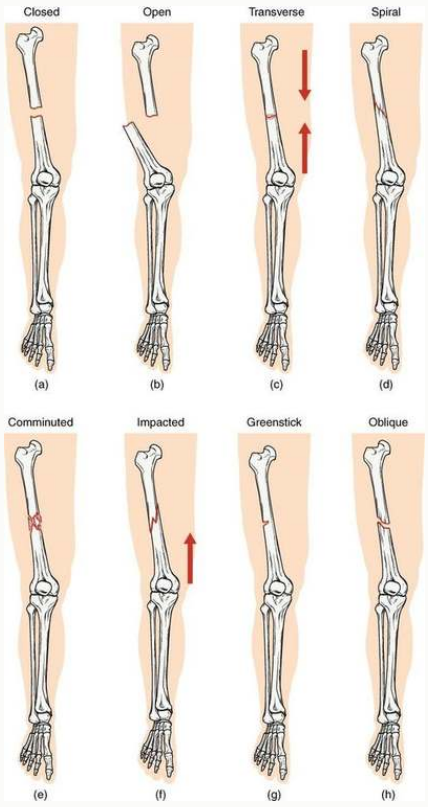

Figure 33.2 Common fracture patterns compared with intact bone: (a) closed, (b) open, (c) transverse, (d) spiral, (e) comminuted, (f) impacted, (g) greenstick and (h) oblique. (credit: "612 Types of Fractures" by OpenStax College/Wikimedia Commons, CC BY 4.0)

Some patients heal slowly or not at all. In a large cohort of more than 309,000 fractures in the United States, 4.9% did not unite (Zura et al., 2016). The odds of **nonunion**, a fracture that fails to heal, were higher with more severe injuries (several fractures, an open fracture, high-energy trauma) and with diabetes, smoking, obesity, osteoporosis, vitamin D deficiency and kidney disease. Some medicines were also linked to higher odds, including opioids alone or with anti-inflammatory drugs and anticoagulants (Zura et al., 2016). Laboratory work shows how some of these factors act: smoking slows the growth of new blood vessels, diabetes keeps inflammation from settling, and anti-inflammatory drugs block an enzyme the callus needs (Bahney et al., 2019). Poor blood supply to the injured bone also delays healing, and older age is linked to inflammation that is slow to settle and fewer repair cells (Bahney et al., 2019). Older adults may therefore need longer support, follow-up and protection from falls while a fracture heals. Nurses can use these links in teaching: stopping smoking, keeping blood glucose in the target range (Chapter 22) and eating well all support the body's repair work. Questions about which pain medicines to use belong with the prescriber and Chapter 5.

First Care After Injury

Life comes before limb. A patient with a fracture after major trauma is first assessed for airway, breathing, circulation and bleeding, as taught in Chapter 6. A long-bone or pelvic fracture can hide a large blood loss (Figure 33.3).

For the injured limb, the nurse supports it and assesses and documents its circulation and nerve function before any splint is applied. Clinicians realign and splint the limb, and the neurovascular assessment is repeated after any reduction or splinting, because these steps can change blood flow or press on nerves (BOA & BAPRAS, 2017). The nurse never tries to straighten a deformed limb alone. Pain relief is part of first care; Chapter 5 covers assessment and multimodal analgesia.

An open fracture needs urgent, specific care. The UK standards for open fractures from BOA and BAPRAS (2017) set out these steps:

- intravenous (IV) prophylactic antibiotics are given as soon as possible, ideally within one hour of the injury;
- the wound is touched only to clear gross contamination and to allow photographs, which are taken when the wound is first exposed so the team does not need to keep reopening it;
- the wound is dressed with gauze soaked in saline under an occlusive film until surgery;
- washing out the wound happens in the operating room, not at the bedside;

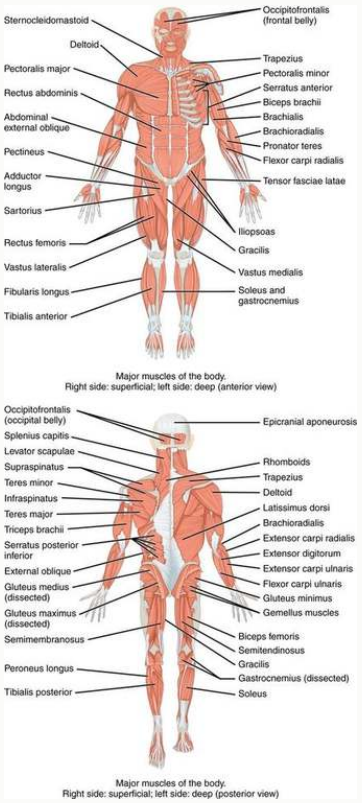

Figure 33.3 Anterior and posterior views of the major skeletal muscles of the human body. (credit: "Figure 11.5, Overview of the Muscular System" by J. Gordon Betts et al./OpenStax, Anatomy and Physiology 2e, CC BY-NC-SA 4.0)

- debridement, the surgical removal of dead and contaminated tissue, is done urgently, at once for heavily contaminated wounds or a limb with poor blood supply.

Wound photographs are part of the health record and follow privacy rules (Chapter 1). Infection prevention is covered in Chapter 4.

Many fractures in older adults follow a fall from standing height. The nurse looks for the cause of the fall, asks about anticoagulants, and checks for head injury and hip pain as well as the obvious fracture. Chapter 8 covers falls and frailty; hip fracture is in section 33.4.

Casts, Splints and Traction

A **cast** is a rigid shell of plaster or fibreglass that wraps around the limb to hold a fracture still. A **back slab** is a splint of plaster or fibreglass moulded along one side of the limb and held on with a bandage. Because it does not wrap all the way around, a back slab leaves room for swelling and is often used soon after injury or surgery. Plaster takes longer to harden than fibreglass: in one Canadian emergency discharge guide, patients with plaster casts are told to avoid weight on the cast for three days, while fibreglass can bear weight right away if weight bearing is allowed (Emergency Care BC, 2024; Figure 33.4).

Some swelling is expected for the first two to three days. For a routine cast, one Canadian discharge guide advises raising the limb above heart level on pillows and using wrapped ice for the first one to three days (Emergency Care BC, 2024). Care is different for a patient at risk of compartment syndrome: consensus guidance from the UK Royal College of Nursing (RCN) advises keeping an injured limb at heart level in bed (RCN, 2022b), and a limb with suspected compartment syndrome is kept at heart level, not raised above it (Donaldson et al., 2014; section 33.2). The nurse checks the skin at the cast edges for rubbing and pressure, pads rough edges as policy allows, and keeps the cast clean and dry. Any new burning or stinging under a cast can mean a pressure area forming (Emergency Care BC, 2024).

Traction is a pulling force applied to a limb to restore and keep the alignment and length of a broken bone. In skin traction, the pull is applied through straps or a stirrup on the skin; in skeletal traction, it is applied through a pin or wire placed through the bone. Both use weights, ropes and pulleys. Traction may be used for a short time, for example while a patient waits for surgery. The Going Deeper box covers its care.

An **external fixator** is a frame outside the body joined to the bone by pins or wires that pass through the skin. It holds the fracture while allowing access to wounds. **Pin-site care** is the cleaning and dressing of the skin where pins enter. The evidence on pin-site care is limited and mostly of poor quality, so no single method has been shown to prevent infection best (Lethaby et al., 2013). RCN consensus guidance suggests cleaning with chlorhexidine in alcohol (or saline if chlorhexidine cannot be used), keeping the sites covered, and changing dressings about weekly unless they are wet, there is heavy drainage or infection is suspected (RCN, 2022a). Local protocols vary, and the nurse follows the one in place. Increasing pain at a pin site, spreading redness, more swelling, more drainage, or the patient bearing less weight than before can signal infection and are reported (RCN, 2022a; Figure 33.5).

Internal fixation uses plates, screws, rods or nails placed in surgery to hold the bone from inside.

PATIENT EDUCATION

Living With a Cast or Splint

- For the first one to three days, rest the limb on pillows and use wrapped ice for short periods while awake, keeping the cast dry (Emergency Care BC, 2024).
- Wiggle your fingers or toes often to keep them from stiffening.

- Keep the cast dry. Cover it with a plastic bag sealed with tape when washing, and do not swim or soak in a bath.
- If your skin itches under the cast, blow cool air into it with a hair dryer. Do not push anything inside the cast, such as a pencil or coat hanger, and do not use powders or lotions under it.
- Do not trim, cut or remove the cast yourself, and do not pull out the padding.
- Put weight on the cast only when your health care team says you may.
- Go to the nearest emergency department at once if you have pain that keeps getting worse or is not eased by your pain medicine, numbness or tingling, fingers or toes that look blue or grey, you cannot move your fingers or toes, the cast feels very tight, or the skin under it stings or burns (Emergency Care BC, 2024).

GOING DEEPER

Traction and External Fixation

Required for RN students; optional for PN students.

Traction works only when the pull is steady and in line. The weights must hang freely, never resting on the bed or floor, and the ropes must stay in their pulley tracks; if the patient slides down the bed until the weights touch the floor, the pull is lost. The nurse follows the local traction policy for the set-up and its checks, and does not lift, remove or change the weights unless an order and policy allow it.

Skin traction presses on the skin and on bony areas such as the heels. The nurse inspects the skin under the straps as policy directs, keeps sheets smooth and dry, and repositions the patient to relieve pressure (Chapter 35). Like a cast or a circumferential bandage, skin traction compresses the limb, so UK consensus guidance counts patients in it as at risk of compartment syndrome and restarts hourly neurovascular checks after any procedure that may affect the limb compartments (RCN, 2022b). Immobility in traction also raises the risk of venous thromboembolism (section 33.2).

For skeletal traction and external fixators, pin sites are cared for as described in section 33.1. The nurse handles the frame and limb as the surgeon's orders and local policy direct, and teaches the patient how to recognize pin-site infection and keep the dressings dry (RCN, 2022a).

Neurovascular Assessment

A **neurovascular assessment** is a check of blood flow and nerve function in a limb below an injury, cast, splint, bandage or surgical site. It finds compartment syndrome, vascular injury and nerve compression early, while they can still be treated. Table 33.1 sets out what the nurse checks.

The most important finding is pain. Pain that is out of proportion to the injury, does not ease with the expected analgesia, or increases when the nurse gently stretches the muscles of the injured compartment is the earliest and most sensitive sign of compartment syndrome (RCN, 2022b). To check pain on passive stretch, the nurse slowly straightens (extends) the fingers or toes of the affected limb without the patient's help (RCN, 2026). Numbness and tingling, weakness, colour change and weak or absent pulses are late signs, so a normal pulse does not rule out compartment syndrome (RCN, 2022b, 2026).

Colour alone is not a reliable guide on every skin tone. For patients whose skin is not white, RCN guidance advises also checking skin temperature, swelling, shininess and mottling, and comparing the injured limb with the other limb (RCN, 2026); these checks are useful for every patient. Patients who cannot report pain, such as those who are unconscious or who have a nerve block or epidural, need closer monitoring, and the nurse seeks medical advice early if compartment syndrome is suspected (RCN, 2026).

The frequency of checks follows the order or protocol. For patients at risk, RCN guidance advises checks at least hourly for the first 24 hours, then every four hours for a further 24 hours if pain is stable, and a return to hourly checks after any procedure that may affect the limb compartments, such as surgery or applying traction (RCN, 2022b). Any abnormal finding is reported at once (RCN, 2026).

Table 33.1 Neurovascular assessment of an injured limb (BOA, 2025; Emergency Care BC, 2024; RCN, 2022b, 2026)

What to check	How to check it	Expected finding	Report at once if
Pain	Ask the patient to rate pain at rest and since the last dose of analgesia; note how much analgesia has been needed	Pain is easing or stable and responds to the ordered analgesia	Pain is out of proportion to the injury, keeps rising or needs more and more analgesia

What to check	How to check it	Expected finding	Report at once if
Pain on passive stretch	Gently extend the fingers or toes beyond the injury while watching the patient's face	Mild discomfort only	Stretching the muscles causes sharp or severe pain
Sensation	Touch the skin on each side of the hand or foot and ask what the patient feels, comparing with the other limb	Normal feeling, the same as the other limb	New numbness, tingling, burning or reduced feeling
Movement	Ask the patient to wiggle and spread the fingers or toes, and to bend and straighten them	Moves fully as the injury and cast allow	New weakness or inability to move
Colour and capillary refill	Look at the skin and nail beds; press a nail bed and watch the colour return; compare with the other limb	Colour and refill match the other limb	Pale, grey, blue or mottled skin, or slow refill
Temperature	Feel the skin with the back of the hand and compare with the other limb	Warm, like the other limb	Cool or cold skin, especially if new
Pulses	Palpate the pulses beyond the injury, or use a Doppler device if the pulse cannot be felt	Pulses present and equal to the other side	A weak or absent pulse (a late sign; a present pulse does not rule out compartment syndrome)
Swelling, cast and dressing	Look at the limb and check the fit of the cast, slab or bandage	Swelling is stable and the cast or bandage does not feel tight	Swelling is increasing, the skin is tight and shiny, or the cast or bandage feels too tight

33.2 Complications After Musculoskeletal Injury

Compartment Syndrome

Muscles in the arms and legs are grouped in **compartments**, each wrapped in tough fascia that does not stretch. **Acute compartment syndrome** is a rise in pressure inside one of these closed compartments, high enough to cut off blood flow to the muscles and nerves within it (BOA, 2025). Bleeding or swelling inside the compartment, or a cast or bandage squeezing it from outside, can start the rise. As pressure climbs, small vessels collapse, tissue becomes starved of oxygen, and muscle and nerve begin to die. Without prompt treatment, the damage to muscle and nerve can become permanent.

UK consensus guidance treats every patient with an acute limb injury, limb surgery, or a cast, skin traction or circumferential bandage as at risk (RCN, 2022b). It lists higher risk with male sex, age 35 or younger, a bleeding disorder or anticoagulant use, closed fractures of the tibia or forearm, a crush injury or long-lasting compression, high-energy trauma including open fractures, and treatment with casts, circumferential bandages or fracture realignment (RCN, 2022b). A hip fracture alone is not usually considered high risk (RCN, 2022b). The nurse teaches at-risk patients and their families the warning signs, gives written information, and asks them to report rising pain or tightness at once (RCN, 2022b).

The early signs are about pain. Pain out of proportion to the injury and pain on passive stretch of the muscles in the compartment are the key early findings (BOA, 2025; RCN, 2022b). A steady rise in the amount of opioid a patient needs is itself a warning. UK standards require the dose and timing of analgesics, especially opioids, to be recorded, and call for a joint decision by the patient, anesthesiologist and surgeon, with an agreed monitoring plan, before a regional nerve block is used in an at-risk patient, because a block can hide the pain (BOA, 2025). Numbness, tingling, weakness, colour change and a weak or absent pulse are late signs that do not help with early diagnosis (RCN, 2022b), so a pulse that can be felt does not rule out compartment syndrome. Late signs can also point to other nerve or blood vessel injuries, and any change is reported at once (RCN, 2022b).

When compartment syndrome is suspected, every nurse acts at once:

- **Notify urgently.** The nurse reports the suspicion to the surgeon or most responsible clinician immediately (RCN, 2022b), using SBAR (Chapter 6). The RPN consults the RN at the same time. This is an emergency, not a concern for the next round.

- **Release pressure.** All circumferential dressings and bandages are loosened or released down to the skin (BOA, 2025; Donaldson et al., 2014). A cast may be split or bivalved (cut along both sides) by a trained clinician, as ordered or as policy allows.
- **Position the limb at heart level.** The limb is kept at the level of the heart, not raised above it, so that arterial blood flow into the compartment is not reduced further (Donaldson et al., 2014). Letting the limb hang down would add to the swelling.
- **Support perfusion.** The nurse helps keep blood pressure normal, gives oxygen to keep saturation at the target the team sets, and stays with the patient (Donaldson et al., 2014; RCN, 2022b).
- **Reassess and record.** The nurse repeats the neurovascular assessment often, records pain scores and all analgesia, and documents the times of each finding, call and action; UK standards expect the limb to be re-evaluated within 30 minutes (BOA, 2025).

If the findings are unclear, the team may measure the pressure inside the compartment (BOA, 2025). A **fasciotomy** is surgery to cut the fascia open along the length of the compartment so the muscle can swell without being crushed. UK standards call for immediate surgical decompression once compartment syndrome is diagnosed (BOA, 2025). The wounds are left open at first and closed or grafted later, so the patient needs wound care (Chapter 35) and support to cope with the scars.

Fat Embolism Syndrome

When a long bone such as the femur breaks, droplets of fat from the marrow can enter the bloodstream and lodge in small vessels of the lungs, brain and skin. **Fat embolism syndrome (FES)** is the illness that can follow. Fat in the blood is common after long-bone fractures, but the full syndrome is much less common. Reported rates vary widely with how studies looked for it (Timon et al., 2021). FES occurs mostly after fractures of the femur, tibial shaft and pelvis, after multiple fractures, and sometimes after hip replacement (Timon et al., 2021).

Signs usually appear 24 to 48 hours after the injury (Timon et al., 2021), and some reports describe onset up to 72 hours (Seixas & Ferreira, 2018; Sogunuru & Moka, 2010). That delay is why a patient who seemed stable on admission can become unwell on the second day. The classic picture combines three groups of findings:

- **Breathing problems**, the most common feature: rapid breathing, shortness of breath and low oxygen saturation, ranging from mild distress to respiratory failure needing a ventilator (Timon et al., 2021).
- **Neurologic changes:** restlessness, confusion, drowsiness and, rarely, seizures or coma (Timon et al., 2021).
- **A petechial rash:** tiny red-purple spots that do not blanch, usually on the head, neck, front of the chest and armpits (Sogunuru & Moka, 2010; Timon et al., 2021) and in the conjunctivae (Seixas & Ferreira, 2018; Sogunuru & Moka, 2010); one report also names the inside of the mouth and skin folds (Seixas & Ferreira, 2018). The rash is not seen in every patient (Sogunuru & Moka, 2010). On every skin tone, the nurse checks the conjunctivae and the inside of the mouth as well as the skin of the upper body.

Fever, a fast heart rate, and a falling hemoglobin and platelet count may also occur (Timon et al., 2021). Several sets of diagnostic criteria exist, but none has been validated or is accepted as a standard; FES is a clinical diagnosis made after other causes, such as pulmonary embolism (Chapter 15), are ruled out (Seixas & Ferreira, 2018; Timon et al., 2021).

There is no specific treatment. Care is supportive: oxygen, close monitoring of breathing and level of consciousness, and ventilation if needed (Timon et al., 2021). Early stabilization of long-bone fractures is thought to lower the risk (Timon et al., 2021). With supportive care, most patients recover fully (Timon et al., 2021). The nurse's role is to recognize the pattern early and escalate at once (Chapter 6).

Other Complications

Venous thromboembolism, a deep vein thrombosis or pulmonary embolism, is a major risk after lower-limb fractures and orthopedic surgery because of immobility, vessel injury and changes in clotting. The nurse watches for calf pain or swelling, sudden shortness of breath or chest pain, and reports them at once. Prevention and anticoagulants are covered in Chapters 7 and 19, and pulmonary embolism in Chapter 15.

Fracture-related infection is a frequent and serious problem after fracture surgery (Metsemakers et al., 2018). When it involves the bone itself, it is called **osteomyelitis**. Open fractures and implants raise the risk. An international expert consensus treats a sinus or

fistula, wound breakdown, or pus draining from the wound as confirming infection (Metsemakers et al., 2018). Earlier signs, such as new redness, warmth, swelling, rising pain or ongoing wound drainage, call for further assessment. Infection is covered in Chapter 4.

Delayed union means healing is slower than expected; nonunion means the fracture has stopped progressing toward healing. Between 5% and 10% of patients have a fracture that fails to heal (Zura et al., 2016). The nurse reports pain or movement at the fracture site that persists long after the expected healing time and supports teaching on the risk factors in section 33.1.

Complex regional pain syndrome, a long-lasting pain condition that can follow a limb injury, is described in Chapter 5.

Table 33.2 compares the serious complications described in this section.

Table 33.2 Serious complications after fractures compared (BOA, 2025; Metsemakers et al., 2018; RCN, 2022b; Seixas & Ferreira, 2018; Timon et al., 2021)

Complication	Usual timing	Early signs	First nursing actions
Compartment syndrome	After injury, surgery, casting or traction; checks are closest in the first 48 hours	Pain out of proportion to the injury; pain on passive stretch; rising analgesic need; a tight, swollen limb	Notify urgently; release bandages to the skin; limb at heart level; support blood pressure and oxygen; reassess and record
Fat embolism syndrome	Usually 24 to 48 hours after a long-bone or pelvic fracture; reported up to 72 hours	Rapid breathing and falling oxygen saturation; new restlessness or confusion; petechiae on the upper body, conjunctivae or mouth	Give oxygen as ordered or per protocol; call for urgent help; monitor breathing and level of consciousness closely
Venous thromboembolism	While mobility is reduced after injury or surgery	Calf pain or swelling; sudden shortness of breath or chest pain	Report at once; see Chapters 15 and 19
Fracture-related infection	Early or late after injury or surgery	New redness, warmth, swelling, rising pain or ongoing drainage; pus or a draining sinus confirms infection	Report and document; wound swab or culture as ordered; follow infection prevention (Chapter 4)
Delayed union or nonunion	Weeks to months after injury	Ongoing pain or movement at the fracture site beyond the expected healing time	Report; review risk factors; support follow-up imaging and appointments

CLINICAL JUDGMENT

Short of Breath on Day Two

Names and details are fictional; this is a composite story.

Malik Haddad, 30, was admitted after a motorcycle crash with a closed fracture of his right femur. He is in skin traction awaiting surgery later today. On day two at 0600, the nurse finds him restless and pulling at his gown.

Recognize cues: His respiratory rate is 28 breaths/min, heart rate 118 beats/min, temperature 38.4 °C and oxygen saturation 89% on room air, down from 97% last evening. He asks the same question twice. When the nurse checks his eyes, there are tiny red spots on the conjunctivae and a few across his upper chest.

Analyze cues: A long-bone fracture, timing of about 36 hours, low oxygen saturation, new confusion and petechiae fit fat embolism syndrome. Pulmonary embolism, pneumonia and opioid effects can also cause some of these findings.

Prioritize hypotheses: Falling oxygenation with a change in mental status is a threat to life. Fat embolism syndrome is the most likely cause; pulmonary embolism must also be ruled out.

Generate solutions: Give oxygen, raise the head of the bed, call for urgent review, monitor closely, and prepare for tests that rule out other causes.

Take action: The nurse applies oxygen as the protocol allows, raises the head of the bed, stays with him and calls the rapid response team, giving an SBAR report that names the petechiae and the confusion (Chapter 6). The nurse checks his traction and leg and records all findings.

Evaluate outcomes: With oxygen, his saturation rises to 94%. He is moved to a higher level of care for monitoring, and his surgery is postponed until his breathing settles.

33.3 Osteoporosis and Bone Health

Osteoporosis

Osteoporosis is a disease in which bones lose mass and strength, so they break more easily. Throughout life, bone is broken down and rebuilt. With age, and especially in women after menopause, breakdown can outpace rebuilding. The bones become thinner and more porous, often with no symptoms until a fracture happens. Common sites of fragility fractures are the forearm, hip, spine, upper arm and pelvis (Public Health Agency of Canada [PHAC], 2024).

In 2019–2020, almost 2.5 million people aged 40 and older in Canada were living with diagnosed osteoporosis, and about 81% of them were women (PHAC, 2024). The risk of a diagnosis doubled every five years between ages 40 and 65. In the same period there were 156 hip fractures per 100,000 people aged 40 and older, and more than one in five people who broke a hip died, from any cause, within the next year (PHAC, 2024). Because osteoporosis usually causes no symptoms, a fracture is often the first sign. Any low-trauma fracture in an adult aged 50 or older is a reason to ask about bone health (Morin et al., 2023). Yet many people are not treated after a fracture. Among people in Canada who had a fracture at a site most linked to osteoporosis, only 21% of those aged 65 and older received a prescription for an osteoporosis medicine, and only 15% of those aged 40 and older had a bone density test; men were less likely to receive any intervention (PHAC, 2024).

Bone mineral density (BMD) is the amount of mineral in a given area of bone, measured with a low-dose X-ray scan called dual-energy X-ray absorptiometry (DXA). A T-score of −2.5 or lower on a BMD test confirms osteoporosis (Morin et al., 2023). Osteoporosis can also be diagnosed clinically in people aged 50 or older who have had a low-trauma fracture of the hip, spine, upper arm or pelvis after age 40, or whose 10-year risk of a major osteoporotic fracture is 20% or higher (Morin et al., 2023).

The Osteoporosis Canada 2023 guideline targets testing by age and risk factors (Morin et al., 2023; Osteoporosis Canada, 2024). For postmenopausal women and for men, it suggests BMD testing for:

- adults aged 70 and older;
- adults aged 65 to 69 with one risk factor;
- adults aged 50 to 64 with a previous osteoporosis-related fracture or at least two risk factors.

Risk factors include a fragility fracture after age 40, glucocorticoid use for more than three months in the past year, two or more falls in the past year, a parent who broke a hip, low body weight, conditions that cause bone loss, current smoking and drinking three or more alcoholic drinks a day (Osteoporosis Canada, 2024). The nurse can screen for clues during assessment, such as height loss or a stooped posture, which can signal spinal fractures. The guideline prefers the Canadian version of the Fracture Risk Assessment Tool (FRAX), which estimates the 10-year chance of a major fracture; the Canadian Association of Radiologists and Osteoporosis Canada (CAROC) tool is also validated (Morin et al., 2023). The guideline recommends medicine for postmenopausal women and men aged 50 and older who have had a hip or spine fracture or two or more osteoporosis-related fractures, who have a 10-year major fracture risk of 20% or more, or who are 70 or older with a T-score of −2.5 or lower; it suggests medicine at some lower levels of risk as well (Morin et al., 2023; Figure 33.6).

Prevention and Treatment

Exercise is central. The guideline found high-certainty evidence that balance and functional training reduces falls. It recommends this training, and suggests progressive resistance training, at least twice a week (Morin et al., 2023). Preventing falls is part of preventing fractures; Chapter 8 covers falls prevention in hospital and at home.

Osteoporosis Canada suggests meeting calcium needs with calcium-rich foods, and taking a daily vitamin D supplement along with vitamin D-rich foods (Osteoporosis Canada, 2024). For people who eat a balanced diet and do not take an osteoporosis medicine, calcium and vitamin D supplements likely have little or no effect on fractures (Morin et al., 2023). Some osteoporosis medicines, however, require enough calcium and vitamin D; for example, people taking denosumab must have adequate supplementation (Amgen Canada, 2026).

Medicines reduce fracture risk in people at high risk. **Antiresorptive** medicines slow bone breakdown; **anabolic** medicines build new bone (Morin et al., 2023). The Medications box lists those named in the guideline and the teaching each needs.

Adults aged 50 and older who break a bone from low trauma need assessment for osteoporosis (Morin et al., 2023). A **fracture liaison service** is a coordinated program that identifies people with a recent fragility fracture and makes sure they are assessed and treated to prevent the next fracture. The Osteoporosis Canada guideline recommends that postmenopausal women and men aged 50 and older with a recent fracture have access to one (Morin et al., 2023). Section 33.4 applies this to hip fracture.

Figure 33.6 Lateral spine X-ray showing osteoporotic wedge compression fractures of the L1 and L2 vertebrae, which can cause height loss and a stooped posture.

MEDICATIONS

Medicines for Osteoporosis

Doses are not given here; follow the current product monograph and prescriber's order (Morin et al., 2023).

- **Oral bisphosphonates (alendronate, risedronate):** Teach the patient to take alendronate first thing in the morning with a full glass of plain water only, swallow it whole, stay upright for at least 30 minutes, and let 30 minutes or more pass before eating, drinking anything else or taking other medicines, including calcium (Sandoz Canada, 2022). Report pain or trouble swallowing, chest pain or new heartburn. The prescriber reviews therapy after several years, because the rare risks of long-term use rise over time (Morin et al., 2023).
- **Zoledronic acid:** a bisphosphonate given by IV infusion.
- **Denosumab:** an injection. Teach the patient not to stop or delay it without a plan from the prescriber, because stopping is linked to rapid bone loss and spinal fractures (Amgen Canada, 2026; Morin et al., 2023). Report tingling or muscle spasms, which can signal low calcium, and signs of skin infection.
- **Teriparatide and romosozumab:** anabolic injections. For people who meet treatment criteria and have had a recent severe spinal fracture, or more than one spinal fracture with a T-score of −2.5 or lower, the guideline suggests seeking advice from an osteoporosis specialist about these medicines (Morin et al., 2023).
- **For bisphosphonates and denosumab:** Keep up good oral hygiene, have a dental check-up if advised before starting, and tell the dentist and prescriber about the medicine before any dental surgery; report jaw pain, loose teeth or a sore that will not heal in the mouth, and new thigh, hip or groin pain (Amgen Canada, 2026; Sandoz Canada, 2022).

33.4 Hip Fracture in Older Adults

A hip fracture is often the event that changes an older adult's life most. A fall that a younger person would walk away from can break the hip of a person with fragile bones, and recovery depends on fast, coordinated care from the first hour. This section follows the

older adult from the emergency department (ED) to home, using the Ontario Health quality standard as the guide (Ontario Health, 2024).

Why Hip Fractures Matter

A **hip fracture** is a break in the upper part of the femur, near the hip joint. In older adults, most hip fractures are fragility fractures (section 33.1): they follow a low-energy fall, such as a fall from standing height, in a person whose bones are weakened by osteoporosis (section 33.3). Falls and frailty, the main reasons older adults fall, are taught in Chapter 8.

Ontario Health's quality standard, *Hip Fracture: Care for People With Fragility Fractures* (2024 update), describes the burden in Ontario. About 12,000 people in the province have a hip fracture each year. Within a year, about 20% have died, and about 20% of people who lived on their own before the fracture have moved to long-term care. Of those who lived independently before, fewer than half can later walk without an aid. Hip fractures cost the Ontario health system nearly $500 million each year (Ontario Health, 2024). For the person, the larger cost is often the loss of independence, a home or a familiar routine.

The type of fracture guides the surgery. A **femoral neck fracture** breaks the narrow neck of the femur just below the ball (femoral head), inside the joint capsule, so it is called an intracapsular fracture. An **intertrochanteric fracture** breaks the femur lower down, between the two bony bumps (trochanters) where hip muscles attach, outside the capsule. The quality standard calls for arthroplasty for most displaced intracapsular fractures; one choice is **hemiarthroplasty**, which replaces only the femoral head and neck with a prosthesis. Stable intertrochanteric fractures are fixed with a sliding hip screw or a nail inside the bone, and unstable intertrochanteric fractures and fractures just below the trochanters (subtrochanteric fractures) are fixed with a nail (Ontario Health, 2024; Figure 33.7).

Figure 33.7 (a) Hip X-ray showing a mildly compressed femoral neck fracture (white arrows) in an older adult after an indoor fall; (b) postoperative X-ray after internal fixation with two parallel pins.

Before Surgery

The quality standard expects the diagnosis within 1 hour of arrival at hospital, transfer to an inpatient unit within 8 hours of arrival, and a pain assessment within 30 minutes of arrival (Ontario Health, 2024). The nurse assesses the injured leg, which is often shortened and turned outward, and checks circulation, movement and sensation below the injury (Table 33.1, section 33.1). The nurse also gathers the person's baseline: usual thinking and memory, mobility, living situation, medications and who makes decisions if the person cannot (Chapter 1). Family members and long-term care staff are often the best source of this baseline, and it is needed later to tell whether confusion is new. The team also asks why the person fell. A fall may follow a faint, a new illness, a medication change or a hazard at home, and the cause shapes the plan to prevent the next fall (Chapter 8). While the person waits on a stretcher or in bed, the nurse protects the heels and sacrum from pressure (Chapter 35).

Pain. Untreated pain adds to distress and is a known contributor to delirium (Chapter 8). The standard calls for multimodal analgesia that includes nonopioid medicines and consideration of a peripheral nerve block, such as a fascia iliaca or femoral nerve block, which numbs the hip region with local anesthetic (Ontario Health, 2024). Pain assessment in people who cannot report pain clearly is taught in Chapter 5.

Timely surgery. The standard states that surgery should take place as early as possible and no later than 48 hours after the person first arrives at any hospital; time spent at a hospital that does not do the surgery counts (Ontario Health, 2024). The nurse helps by preparing the person promptly: fasting as ordered, blood work, consent (Chapter 7) and a review of anticoagulants, which may need planning or reversal (Chapter 19).

Delirium prevention. The standard calls for screening for delirium at the first assessment, using a standardized, validated tool, and then at least every 12 hours while in hospital, whenever the person moves to a new setting and whenever their medical condition changes (Ontario Health, 2024). Prevention starts in the ED: glasses and hearing aids, a calm space, family presence, fluids and good pain control (Chapter 8).

After Surgery

Mobilization. The standard expects the person to reach weight bearing as tolerated in the first 24 hours after surgery and then to be mobilized every day, moving step by step from sitting on the edge of the bed to assisted walking (Ontario Health, 2024). Early movement protects the lungs, skin and muscles and helps prevent delirium and loss of function. Before each move, the nurse checks vital signs, oxygen saturation, pain and alertness, and stops if the person becomes faint, short of breath or newly drowsy (Chapter 6).

Delirium and pain. Screening continues at least every 12 hours (Ontario Health, 2024). A new or worse confusion is a cue to look for causes, such as low oxygen, pain, urinary retention, infection, dehydration, low hemoglobin and medications, and to report it (Chapter 8). Pain is reassessed with movement, not only at rest, because pain that blocks walking delays recovery (Chapter 5).

Bleeding and anemia. Hip fracture and its surgery cause blood loss, and hemoglobin often falls in the days after surgery. The standard states that a person who has no symptoms of anemia and a postoperative hemoglobin of at least 80 g/L should not receive a transfusion (Ontario Health, 2024). The nurse watches for symptoms such as dizziness, a fast heart rate, low blood pressure, shortness of breath and new confusion, and reports them (Chapter 20).

Geriatric care. The standard asks for interprofessional care that follows geriatric principles, including nutrition, hydration, careful use of urinary catheters, pressure injury risk assessment, medication review, VTE prevention and assessment of fall risk (Ontario Health, 2024). The nurse removes catheters as soon as allowed, watches for urinary retention and constipation, and encourages food and fluids. Many older adults arrive undernourished or eat little after surgery, so the nurse tracks intake, offers help with meals and refers to the dietitian when intake stays low. The standard also asks that the person and family receive information tailored to them, spoken and in writing or another format, at the right times (Ontario Health, 2024). VTE prophylaxis is described in section 33.5 and Chapter 19; pressure injury prevention is taught in Chapter 35.

Secondary fracture prevention. One fragility fracture signals a high risk of another. **Secondary fracture prevention** is care that aims to prevent the next fracture by finding and treating osteoporosis and reducing falls. The standard calls for a clinician with expertise in osteoporosis to assess fracture risk during the hospital stay, for osteoporosis medicine to be offered when appropriate, and for access to a fracture liaison service (section 33.3) to coordinate this care (Ontario Health, 2024).

Rehabilitation and home. The standard calls for an interprofessional rehabilitation program, in hospital, in the community or both, that aims to return the person to their function before the fracture. It also calls for information that is tailored to the person and family, a scheduled primary care visit no more than 2 weeks after discharge and an orthopedic follow-up no more than 12 weeks after surgery (Ontario Health, 2024) (Table 33.3).

Equity. Because the 48-hour clock starts at the first hospital, people in rural, remote and northern communities who must be transferred lose time before they reach a surgeon. Residents of long-term care homes are often frail and may live with dementia, so the nurse obtains their baseline from the home and shares a clear plan at transfer. First Nations, Inuit and Métis older adults may be flown far from family and community for surgery; culturally safe care involves family, interpreters where needed and early links with community health services for the return home (Chapter 2).

Table 33.3 Care of the older adult with a hip fracture, from arrival to home (Ontario Health, 2024; original wording)

Phase	Nursing priorities	Team members	What to watch for
Arrival in the emergency department	Assess pain within 30 minutes; check circulation, movement and sensation of the leg; learn the person's baseline thinking and function; screen for delirium	ED physician, nurses, anesthesia (nerve block), family	Uncontrolled pain, delirium, dehydration, anticoagulant use
Waiting for surgery	Prepare for surgery quickly; keep pain controlled; keep glasses, hearing aids and family close; give fluids as ordered	Orthopedic surgeon, anesthesia, nurses, pharmacist	Delays beyond 48 hours from first hospital arrival; skin breakdown; confusion
Days 0 to 2 after surgery	Bear weight as tolerated within 24 hours; mobilize at least daily; screen for delirium every 12 hours; manage pain with movement; remove the catheter early	Nurses, physiotherapist, occupational therapist, physician, dietitian	Low oxygen saturation, falling hemoglobin with symptoms, urinary retention, VTE signs, pressure injury
Recovery on the unit	Support nutrition and bowel function; review medications; start secondary fracture prevention; teach the person and family	Interprofessional team, osteoporosis clinician or fracture liaison service, pharmacist	Ongoing delirium, poor intake, falls, low mood
Transition to rehabilitation or home	Share a clear plan; arrange rehabilitation; book primary care within 2 weeks and orthopedic follow-up within 12 weeks	Rehabilitation team, home and community care, primary care, family	Loss of function, a second fall, missed osteoporosis treatment

CANADIAN CONTEXT

Hip Fracture Surgery in Canada

Canada has tracked how fast people with a hip fracture reach surgery for two decades. In December 2005, the federal, provincial and territorial governments agreed on a benchmark of hip fracture repair within 48 hours (Canadian Institute for Health Information [CIHI], n.d.-a). CIHI now reports two related indicators. One measures the risk-adjusted share of adults (18 and older) whose hip fracture surgery happens within 48 hours of their first admission to an acute care hospital; when a person is transferred, the whole wait is counted against the hospital that does the surgery (CIHI, n.d.-a). The other counts the hours from first registration in an ED to surgery (CIHI, n.d.-b).

CIHI explains that timely surgery leads to better outcomes and reduces the chance of lasting pain, complications and death (CIHI, n.d.-a). In its 2025 report on wait times for priority procedures, CIHI reported that 83% of patients had hip fracture repair within 48 hours in 2024, 3 percentage points lower than in 2019 (CIHI, 2025). In Ontario, about a quarter of patients waited longer than 48 hours in 2022/23, and the share varied from 3% to 69% across hospitals (Ontario Health, 2024). Nurses help close these gaps by preparing patients quickly and by escalating delays.

PRACTICE STORY

Up on Day One

Names and details are fictional; this is a composite story.

Nurse: Samira Darwish, RPN. Years in practice: 6. Setting: orthopedic unit, Ontario.

Mr. Doucette was 84, a retired mail carrier who told me twice before breakfast that he had walked every street in town. He'd had his hip fixed with a nail the afternoon before, after a fall in his kitchen. The order said weight bearing as tolerated, and the physiotherapist was booked for the afternoon. My plan was to get him sitting at the edge of the bed, then standing with the walker, before lunch.

At 0900 he was chatty and sharp. His oxygen saturation was 95% on room air, and his pain was 4 out of 10 after his morning medicines. At 1100, when I came back with the walker, he was harder to wake. He answered my questions, but his eyes kept closing and he couldn't tell me where he was. I sat him up slowly and dangled his legs. His saturation read 88%, and his breathing was quicker than before.

I didn't stand him. I lowered him back with the head of the bed up, stayed with him, and pressed the call bell for the RN on my team, Grace. While I waited, I rechecked the saturation on a warm finger and took a full set of vital signs. His heart rate had gone from 78 to 102. I checked his medication record: he'd had an opioid dose at 0930.

> When Grace came, I gave her what I had in order: what I'd found at 0900, what had changed, the numbers and the opioid time. She assessed him, started oxygen per our protocol and called the surgical resident. Later that day they were looking into a possible pulmonary embolism.
>
> The next morning, Mr. Doucette asked when he could go for his walk. I told him soon, and that we'd do it together.
>
> Reflect: Samira's plan was to mobilize Mr. Doucette, but she stopped when he changed. How did his new drowsiness, falling saturation and faster heart rate change the context of his care, and why did that call for consulting the RN?

33.5 Joint Replacement and Spine Surgery

Joint replacement is one of the most common operations in Canada, and spine surgery relieves pain and nerve pressure for many adults. Both rely on good preparation, early movement and clear teaching for home.

Hip and Knee Replacement

In a **total hip arthroplasty** (THA), the surgeon replaces the ball of the femur and lines the hip socket with artificial parts. In a **total knee arthroplasty** (TKA), the worn surfaces of the femur and tibia, and often the kneecap, are resurfaced. Most people have these operations for osteoarthritis that limits walking and sleep despite other treatment (Chapter 34). A hip fracture may also be treated with a hemiarthroplasty or a THA (section 33.4) (Figure 33.8).

The Canadian Joint Replacement Registry (CJRR), run by CIHI, reported 175,242 hip and knee replacements in 2024–2025, 5.3% more than the year before and 26.5% more than in 2019–2020. Day surgery is growing fast: it accounted for 35.8% of hip and 31.1% of knee replacements for osteoarthritis, increases of 3.5-fold and 4.5-fold, respectively, since 2020–2021. In Ontario, Manitoba and Alberta, the provinces with these data, 9 in 10 patients reported 1 year after surgery that their outcomes had improved and that they were satisfied (CIHI, 2026).

Figure 33.8 Anteroposterior pelvic X-ray showing a right total hip arthroplasty, with a metal stem in the femur and a prosthetic ball seated in the replaced hip socket.

Before surgery. The Enhanced Recovery After Surgery (ERAS) Society recommends routine preoperative education, which reduces anxiety, and recommends finding and correcting anemia before surgery (Wainwright et al., 2020). The nurse teaches what to expect, how pain will be managed (Chapter 5), how to use a walker or crutches, and how to prepare the home. Preparation also lowers infection risk: anemia, malnutrition, obesity and tobacco use are risk factors for joint infection that can be changed before surgery, and diabetes with poor glucose control raises the risk as well (Patel, 2023). The nurse supports stopping smoking and good glucose control (Chapter 22). **Prehabilitation** means exercise and conditioning before surgery to improve recovery afterward. The ERAS Society states that the evidence does not show physiotherapy before surgery to be an essential part of care, so programs vary by surgeon and region (Wainwright et al., 2020).

After surgery. ERAS recommends mobilizing patients as soon as they are able, an opioid-sparing multimodal approach to pain, no routine wound drains and no routine urinary catheters; when a catheter is used, it comes out once the person can void, ideally within 24 hours (Wainwright et al., 2020). Objective discharge criteria, such as getting dressed, transferring to the bed and toilet, and walking a set distance with a walker or crutches, help people go directly home (Wainwright et al., 2020). In same-day pathways, the person meets these criteria before leaving the hospital on the day of surgery. Before discharge, the nurse confirms that the person has voided, that pain is controlled with oral medicines, that they can move safely with their aid, that an adult will be with them at home, and that they know whom to call.

Hip precautions. Hip precautions are limits on bending, crossing the legs and turning the leg inward, traditionally taught after THA done through a posterior (back) approach to prevent dislocation. A 2023 systematic review and meta-analysis found that precautions after posterior-approach THA may make little or no difference to dislocation in the first 3 months (low- to very-low-certainty evidence), and concluded that current evidence does not support prescribing them routinely (Korfitsen et al., 2023). Practice therefore varies: the nurse teaches the precautions that the surgeon's protocol orders, no more and no less, and makes sure the person and family know them.

VTE prophylaxis. For THA and TKA, an international guideline from the American Society of Hematology (ASH) suggests either acetylsalicylic acid (ASA) or an anticoagulant; when an anticoagulant is used, it suggests a direct oral anticoagulant (DOAC), such as apixaban or rivaroxaban, over a low-molecular-weight heparin (LMWH), such as enoxaparin or dalteparin. After hip fracture surgery, it suggests drug prophylaxis with an LMWH or unfractionated heparin (Anderson et al., 2019). When drug prophylaxis is not used, it suggests mechanical prophylaxis, preferring intermittent pneumatic compression over stockings (Anderson et al., 2019). The nurse gives the ordered regimen, teaches how long to continue it at home, and teaches the signs of deep vein thrombosis and pulmonary embolism (Chapters 15 and 19).

Complications. A **hip dislocation** occurs when the ball of the prosthesis comes out of the socket. It usually follows a low-energy event, such as a movement that takes the hip beyond its safe range, and causes sudden pain; after a posterior dislocation, the leg is typically shortened and turned inward (Dawson-Amoah et al., 2018). The person usually cannot move or bear weight on the leg. The nurse keeps the person still, checks circulation and sensation in the foot (section 33.1) and notifies the surgeon at once. A **periprosthetic joint infection** is an infection of the artificial joint and the tissue around it. Pain in the joint is the symptom seen most often, and fever is often absent; redness, swelling and warmth may be present, and a draining tract from the joint to the skin is a sure sign (Patel, 2023). The risk is highest soon after surgery but lasts for the life of the joint. A Canadian population-based study cited in one review found that about 0.5% of people who had a hip replacement developed a joint infection within 1 year (Patel, 2023). Wound care is taught in Chapter 35, and infection basics in Chapter 4. After TKA, regaining the ability to bend and fully straighten the knee is a main goal of recovery, so the nurse gives analgesia before exercise sessions and supports the exercises the physiotherapist teaches.

Spine Surgery in Brief

Spine surgery relieves pressure on the spinal cord or nerve roots, or stabilizes the spine. A **laminectomy** removes part of the lamina, the bony arch at the back of a vertebra, to make more room for nerves. A **discectomy** removes the part of a herniated disc that presses on a nerve root. A **spinal fusion** joins two or more vertebrae with a bone graft, often held with screws and rods, so that they heal as one bone. These operations are most often done for a herniated disc or a narrowed spinal canal that causes leg pain, numbness or weakness despite other treatment, or for an unstable spine. Spinal cord injury is taught in Chapter 32.

Neurologic and limb checks. Before surgery, the nurse records a baseline of leg (or arm, for neck surgery) strength, sensation and bladder and bowel function. After surgery, the nurse compares each check with the baseline and with the other side. New or worsening weakness or numbness, reduced feeling in the saddle area (the buttocks, perineum and inner thighs) or new bladder or bowel problems are reported at once. These can signal pressure on the nerves from blood collecting in the spinal canal (spinal epidural hematoma), a rare but serious complication that needs early detection and prompt surgery (Liu et al., 2025). A tear in the dura, the membrane around the spinal cord and nerve roots, can leak cerebrospinal fluid and cause head or neck pain that changes with posture (Floman et al., 2015). The nurse reports a new or worsening headache, unusual drainage on the dressing or any drop in alertness.

Ongoing care. The ERAS Society recommends preoperative education, early mobilization and physiotherapy, multimodal analgesia, risk-based prevention of nausea and vomiting, early return to a normal diet, and mechanical VTE prophylaxis with early walking for all patients, with drug prophylaxis reserved for higher-risk groups (Debono et al., 2021). The nurse turns the person by log rolling, keeping the shoulders and hips moving together, when ordered. Urinary catheters are not used routinely after short fusions and, when used, are removed within hours; the nurse then checks that the person empties the bladder, using a bladder scan as ordered, because urinary retention can occur (Debono et al., 2021). Teaching covers bending, lifting and driving limits as the surgeon orders, walking every day and signs to report.

PATIENT EDUCATION

Going Home After a Hip or Knee Replacement

- **Keep moving:** walk several times a day with your walker or crutches, and do the exercises your physiotherapist taught you. Short, frequent walks help more than one long one.
- **Follow your own instructions:** do the hip movements and limits your surgeon gave you. Rules differ between surgeons, so ask before following advice from friends or the internet.
- **Prevent falls:** clear floors of rugs and cords, use a night light, wear shoes that hold your heel, and use a raised toilet seat or grab bars if they were recommended.
- **Take your blood clot medicine** for as long as you were told, even if you feel well.
- **Manage pain:** take pain medicines as directed, especially before exercises, and use ice as taught.
- **Look after your incision:** keep it clean and dry, and don't soak it in a bath, pool or hot tub until your surgeon says so.
- **Call your surgeon's office** for redness, warmth, swelling or drainage from the incision; a fever; or pain that keeps getting worse.
- **Go to the nearest ED or call 9-1-1** for sudden severe hip pain with a leg that looks shorter or turned, chest pain or sudden shortness of breath. New calf pain or swelling needs care the same day.

GOING DEEPER

Blood Loss and Anemia After Joint and Hip Fracture Surgery

Required for RN students; optional for PN students.

Blood is lost during joint replacement and hip fracture surgery, and more can be lost into the tissues afterward, so hemoglobin may keep falling in the first days after surgery.

Before surgery. The ERAS Society recommends identifying, investigating and correcting anemia before planned hip and knee replacement (Wainwright et al., 2020).

During surgery. The ERAS Society gives a strong recommendation, based on high-quality evidence, for tranexamic acid to reduce blood loss and the need for transfusion in hip and knee replacement (Wainwright et al., 2020). Tranexamic acid slows the breakdown of clots.

Transfusion decisions. The Ontario standard for hip fracture states that a person without symptoms whose postoperative hemoglobin is 80 g/L or more should not be transfused (Ontario Health, 2024). The 2023 AABB international guideline recommends considering transfusion for most hospitalized adults who are hemodynamically stable when hemoglobin is below 70 g/L; clinicians may choose 80 g/L for people having orthopedic surgery or with existing cardiovascular disease (Carson et al., 2023). The Canadian Society for Transfusion Medicine's Choosing Wisely list sets no number; it bases decisions on symptoms and hemoglobin and advises transfusing a single unit of red cells at a time for stable patients who are not bleeding (Canadian Society for Transfusion Medicine [CSTM], 2025). A number alone does not decide: chest pain, a rising heart rate, low blood pressure, shortness of breath or new confusion with a falling hemoglobin is reported at once. Transfusion safety is taught in Chapter 20.

33.6 Amputation

An **amputation** is the removal of all or part of a limb. Most amputations in Canada are of the lower limb, and many follow years of vascular disease. Caring well for a person after amputation means caring for the residual limb, preventing complications and supporting grief, body image and rehabilitation.

Why Amputations Happen

Peripheral arterial disease (PAD) narrows the arteries to the legs (Chapter 19), and diabetes damages nerves and blood vessels so that foot wounds heal poorly (Chapter 22). Together they cause most lower-limb amputations. In an Ontario study of adults 40 and older who had an amputation related to diabetes or PAD from 2005 to 2016, about 82% of the 20,062 patients had diabetes, about 94% had PAD and about 76% had both; about 64% had a major amputation above the ankle. After falling from 2005 to 2010, the rate of amputation rose again, reaching 10.0 per 100,000 adults aged 40 or older by early 2016 (Hussain et al., 2019). Trauma, severe infection and cancer are other causes.

The burden is not shared equally. Among Ontarians with diabetes, First Nations people had lower-limb amputations 3 to 5 times as often as other Ontarians with diabetes from 1995/96 to 2014/15, and more than 6 times as often among those 44 and younger, while rates of surgery to restore blood flow were similar (Shah et al., 2019). Risk was highest in remote communities. The authors point to underdiagnosed or undertreated PAD, poor access to specialized wound care and rehabilitation, and the social, economic and cultural conditions that shape health (Shah et al., 2019). These are structural causes rooted in colonial policies, distance and underfunded services, not in the people themselves (Chapter 2). The study was a research partnership with the Chiefs of Ontario, whose Data Governance Committee approved it; this book respects First Nations data governance under the OCAP® principles (Chapter 2). Where the person wishes, the nurse works with their community's own health services during care and in planning the return home.

Care After Amputation

The residual limb. The **residual limb** is the part of the limb that remains after amputation. The nurse checks the dressing for bleeding and drainage, assesses pain, and watches the incision for signs of infection. Swelling must be controlled so that the limb takes a stable shape for a prosthesis. A Canadian rapid review by CADTH (now Canada's Drug Agency) found that removable rigid dressings after below-knee amputation may reduce limb volume faster in the first month than soft dressings, with similar complications, but the evidence was of low certainty (Vu & Butcher, 2022). The team chooses the dressing, elastic wrap or shrinker sock, and the nurse applies it as ordered and checks the skin under it. Before discharge, the nurse teaches the person to inspect the residual limb every day, using a mirror if needed. For a person with diabetes or PAD, the remaining foot is at high risk too, so daily foot checks and proper footwear are taught (Chapter 22).

Preventing contracture. A **contracture** is a fixed shortening of muscles and joint tissues that stops a joint from straightening. After an above-knee amputation, the hip tends to stay bent; after a below-knee amputation, the knee does. A contracture can make fitting a prosthesis difficult or impossible. The nurse avoids propping the residual limb on pillows or letting it hang over the edge of the bed, encourages lying prone for periods each day as ordered and tolerated, keeps the knee as straight as possible after a below-knee amputation, and supports the exercises the physiotherapist teaches (National Rehabilitation Hospital, n.d.). In one trial in that review, a person treated with an elastic bandage developed a knee flexion contracture (Vu & Butcher, 2022).

Phantom limb sensation and pain. Many people feel that the removed limb is still there, which is called phantom limb sensation. **Phantom limb pain** is pain felt in the part of the limb that has been removed. It is real pain. A 2020 meta-analysis found a pooled prevalence of 64%, and identified ongoing pain before surgery, a higher amputation level, pain in the residual limb, lower-limb amputation and phantom sensations as risk factors (Limakatso et al., 2020). The nurse asks about phantom pain directly, describes it as common and real, and treats it with the team (Chapter 5).

Grief, body image and function. Losing a limb is a loss of function, identity and often work and independence. The nurse makes room for grief and anger, notices signs of depression and refers as needed, and involves family in care when the person wishes. Some people find meeting someone who lives with an amputation helpful, and the team can suggest peer support where it exists.

Rehabilitation and the prosthesis. A **prosthesis** is an artificial device that replaces a missing body part. Rehabilitation teams teach transfers, wheelchair use, strengthening and, when the limb is ready, walking with a prosthesis. Funding varies by province and insurance. The War Amps Adult Amputee Program provides financial help toward the cost of artificial limbs for adults living in Canada after provincial or private coverage is used, along with information on living with an amputation, including phantom limb pain (The War Amps, n.d.; Figure 33.9).

Figure 33.9 A transtibial (below-knee) prosthesis in use during outdoor walking, cropped to the lower limbs. (credit: modification of "Transtibial amputee with Lunaris foot prosthesis" by Axiles Bionics/Wikimedia Commons, CC BY-SA 2.0)

33.7 Mobility and Safe Patient Handling

Moving a patient safely protects both the patient and the nurse. Bed rest weakens muscles and leads quickly to loss of function in older adults, so mobility is part of treatment, not an extra (Chapter 8). **Functional decline** is a loss of the ability to carry out daily activities, such as walking, dressing and toileting, that a person could do before an illness or hospital stay. On an orthopedic unit, the person's weight-bearing order (non-weight-bearing, partial weight-bearing or weight-bearing as tolerated) and any movement limits shape every move. At the same time, manual lifting injures health care workers.

Injury Risk for Nurses

Musculoskeletal disorders are common among Ontario health care workers. Using 2021 Workplace Safety and Insurance Board (WSIB) data, the Centre of Research Expertise for the Prevention of Musculoskeletal Disorders (CRE-MSD) reports that the lost-time injury rate for these disorders in health care was about twice the provincial average. Back injuries made up 48% of lost-time claims, and 48% of musculoskeletal injuries in health care were linked to lifting, transferring or repositioning clients (CRE-MSD, 2025). The highest rates were in residential care facilities for older adults, home care services and hospitals.

Safe patient handling is an organized approach that uses assessment, equipment, policy and training to move patients without manual lifting where possible. CRE-MSD notes that effective programs involve more than equipment, and that patients have fewer falls, skin tears and pressure injuries when they are in place (CRE-MSD, 2025). Good body mechanics alone do not make manual lifting of an adult safe.

Assessing Before Every Move

Before each move, the nurse assesses what the person can do today: alertness and ability to follow directions, ability to bear weight, sitting balance and trunk control, pain, lines and drains, and any weight-bearing or movement orders. The Public Services Health & Safety Association (PSHSA) client mobility plan records the method and equipment for each type of move (repositioning, transfers that use the person's own weight bearing, lifts for people who cannot bear weight, and lateral transfers) so that every staff member moves the person the same way (PSHSA, 2025). Abilities change after surgery, with delirium or with a new illness, so the nurse

reassesses and updates the plan. The nurse also explains each move before starting, asks the person to help as much as they can, and respects their preferences and dignity. The plan is shared at handover and kept where every staff member can see it.

Choosing Equipment

A **mechanical lift** is a device that raises and moves a person in a sling, from the floor or a ceiling track, so that staff do not bear the person's weight. Sit-to-stand devices help people who can bear some weight, and slider sheets reduce friction when repositioning a person in bed or moving them to a stretcher (PSHSA, 2025). CRE-MSD cautions that equipment that gives more support than needed can take away chances for the person to work their own muscles, and that clinical judgment and assessment remain the main guide to choosing a method (CRE-MSD, 2024). The aim is the least support that is safe (Table 33.4). Before each use, the nurse checks that the lift is charged and working, that the sling is the right type and size for the person, and that enough trained staff are present. People with a larger body size need equipment rated for their weight; the PSHSA plan lists bariatric portable and ceiling lifts (PSHSA, 2025).

Walking aids, such as canes, walkers and crutches, are chosen and fitted by the physiotherapist. The nurse checks that the aid is the right height and in good repair, that the person uses it as taught, and that the path is clear. Employer policy sets the training, the number of staff for each lift and when equipment must be used. Employer policy also sets the response when a person starts to fall or is found on the floor: the nurse calls for help, assesses for injury before the person is moved, and uses the equipment that policy requires to get them up (Chapter 8).

Table 33.4 Matching the move to the person: mobility and handling equipment (PSHSA, 2025; CRE-MSD, 2024; original wording)

What the person can do	Safe approach	Equipment	Nursing points
Moves independently and safely	Supervise or stand by; encourage independence	Walking aid if prescribed	Check footwear, path and the aid; reassess after any change
Bears weight and follows directions, needs a little help	Assist with one staff member as the plan states	Transfer belt, walking aid	Stand at the person's side; stop if dizzy or short of breath
Bears some weight, has fair sitting balance	Sit-to-stand transfer	Sit-to-stand device, correct sling size	Confirm weight-bearing orders; watch for fatigue
Cannot bear weight, or is unable to follow directions	Full mechanical lift with the number of staff policy requires	Ceiling or portable lift, correct sling	Check the sling and lift before use; never lift manually
Needs repositioning in bed or a move to a stretcher	Slide rather than lift	Slider sheet, lateral transfer device	Use enough staff; protect skin, lines and the surgical site

SCOPE IN PRACTICE

Orthopedic Care and Who Does What

The College of Nurses of Ontario (CNO) Scope of Practice standard asks each nurse to consider authority, competence and context before taking on an activity (Chapter 1, section 1.3). On an orthopedic unit, RNs and RPNs share much of the work, and employer policy and the province or territory shape the details.

- **Every nurse:** performs neurovascular checks, recognizes signs of compartment syndrome, fat embolism, bleeding, VTE or delirium, acts at once and escalates (sections 33.1 and 33.2; Chapter 6). An RPN consults the RN as the patient's needs change, and every nurse who sees deterioration acts immediately.
- **Traction, external fixators and casts:** caring for a patient in traction, pin-site care, bivalving a cast or applying a splint depend on an order where needed, employer policy and the nurse's competence. A nurse who has not been taught a skill seeks education and supervision first.
- **Mobilization:** nurses mobilize patients as the plan and orders allow and work with physiotherapists on progression. Using a mechanical lift requires training on that device.
- **Context:** a patient whose condition is changing quickly, such as one who is newly hypoxic or confused, may need the RN to take a larger role. Assigning by stability is a common employer practice, not a CNO rule.

Chapter 33 Summary

33.1 Fractures and Their Care

- Fractures are described as closed or open, complete or incomplete, displaced, comminuted, pathologic or fragility fractures; the terms guide care.
- Bone heals through overlapping phases of inflammation, new blood vessel growth, callus formation and remodelling. Severe injury, smoking, diabetes and some medicines raise the odds of nonunion.
- Open fractures need IV antibiotics as soon as possible, ideally within one hour, minimal wound handling, photographs and a saline-soaked dressing until surgery.
- Cast, traction and external fixator care protect the skin and alignment. Pin-site care follows local protocol, because no single method has been shown to be best.
- Neurovascular assessment compares the injured limb with the other limb. Pain out of proportion and pain on passive stretch are the earliest warning signs, and colour alone is not a reliable guide on every skin tone.

33.2 Complications After Musculoskeletal Injury

- Compartment syndrome is a surgical emergency. Pain is the early sign; numbness, weakness, colour change and absent pulses are late.
- When compartment syndrome is suspected, the nurse notifies urgently, releases bandages to the skin, keeps the limb at heart level and reassesses.
- Fat embolism syndrome usually appears 24 to 48 hours after a long-bone or pelvic fracture, with low oxygen, confusion and petechiae; care is supportive and escalation is urgent.
- Other complications include venous thromboembolism, fracture-related infection and osteomyelitis, and delayed union or nonunion.

33.3 Osteoporosis and Bone Health

- Almost 2.5 million people aged 40 and older in Canada were living with diagnosed osteoporosis in 2019–2020, and most people with a fracture linked to osteoporosis are not tested or treated.
- The Osteoporosis Canada 2023 guideline targets BMD testing by age and risk factors and prefers the Canadian FRAX tool to estimate 10-year fracture risk.
- Balance, functional and resistance exercise and falls prevention are central. Medicines include bisphosphonates, denosumab, teriparatide and romosozumab.
- Nurses teach how to take oral bisphosphonates safely, not to stop denosumab without a plan, and to report jaw or thigh pain; fracture liaison services close the treatment gap.

33.4 Hip Fracture in Older Adults

- Most hip fractures in older adults are fragility fractures after a low-energy fall; in Ontario about 12,000 occur each year, and about 1 in 5 people die within a year.
- Ontario Health's 2024 quality standard calls for surgery no later than 48 hours after the person first arrives at any hospital, pain assessment within 30 minutes and consideration of a nerve block.
- After surgery, the person reaches weight bearing as tolerated in the first 24 hours, is mobilized at least daily and is screened for delirium at least every 12 hours.
- People without symptoms whose hemoglobin is 80 g/L or higher are not transfused under the standard; symptoms of anemia are reported.
- Secondary fracture prevention, interprofessional rehabilitation and follow-up within 2 and 12 weeks complete the plan; rural, long-term care and First Nations, Inuit and Métis patients need plans that account for distance and transitions.

33.5 Joint Replacement and Spine Surgery

- CIHI's joint replacement registry reported 175,242 hip and knee replacements in 2024–2025, with a fast rise in day surgery.
- Enhanced recovery care includes preoperative education, early mobilization, multimodal analgesia, no routine drains or catheters and objective discharge criteria.
- Evidence does not support routine hip precautions after posterior-approach THA; the nurse teaches what the surgeon's protocol orders.
- VTE prophylaxis follows the order (the international ASH guideline suggests ASA or an anticoagulant after THA or TKA); dislocation and periprosthetic joint infection are reported at once.
- After spine surgery, the nurse compares leg strength and sensation with the baseline, reports new deficits at once and checks for urinary retention.

33.6 Amputation

- Diabetes and PAD underlie most lower-limb amputations in Ontario, and rates rose again after 2010.
- First Nations people with diabetes in Ontario had amputations 3 to 5 times as often as other Ontarians with diabetes (1995/96 to 2014/15), reflecting structural barriers to care.
- Nursing care protects the residual limb, controls swelling and prevents hip and knee contractures through positioning and exercise.
- Phantom limb pain affects about 64% of people with amputation and is real pain that needs treatment.
- Grief, body image, rehabilitation and funding for a prosthesis are part of the plan.

33.7 Mobility and Safe Patient Handling

- Mobility is treatment, and bed rest leads to functional decline in older adults.
- Ontario health care workers have lost-time musculoskeletal injury rates roughly double the Ontario average, and almost half of these injuries are linked to moving clients.
- The nurse assesses the person before every move and follows and updates the mobility plan.
- Equipment is matched to the person's abilities, using the least support that is safe, and no adult is lifted manually.
- After a fall, the nurse calls for help, assesses for injury and uses the equipment policy requires to get the person up.

Key Terms (42)

amputation: The removal of all or part of a limb.

back slab: A plaster or fibreglass splint moulded along one side of a limb and held on with a bandage, leaving room for swelling.

bone mineral density (BMD): The amount of mineral in a given area of bone, measured with dual-energy X-ray absorptiometry (DXA).

cast: A rigid shell of plaster or fibreglass that wraps around a limb to hold a fracture still.

closed fracture: A fracture in which the skin over the break is intact.

comminuted fracture: A fracture in which the bone breaks into three or more pieces.

compartment syndrome: A rise in pressure within a closed muscle compartment that cuts off blood flow to the muscles and nerves inside it; a surgical emergency.

contracture: A fixed shortening of muscles and joint tissues that stops a joint from straightening fully.

discectomy: Surgery that removes the part of a herniated disc that presses on a nerve root.

external fixator: A frame outside the body joined to the bone by pins or wires that pass through the skin, used to hold a fracture still.

fasciotomy: Surgery that cuts open the fascia along a muscle compartment to relieve pressure.

fat embolism syndrome (FES): An illness, usually after a long-bone or pelvic fracture, in which fat droplets in the blood cause breathing problems, neurologic changes and a petechial rash.

femoral neck fracture: A break in the narrow neck of the femur just below the femoral head, inside the hip joint capsule (an intracapsular fracture).

fracture: A break in the continuity of a bone.

fracture liaison service: A coordinated program that identifies people with a recent fragility fracture and makes sure they are assessed and treated to prevent another fracture.

fragility fracture: A fracture from low trauma, such as a fall from standing height, that would not normally break a healthy bone.

hemiarthroplasty: Surgery that replaces the femoral head and neck with a prosthesis while leaving the hip socket in place.

hip dislocation: Displacement of the ball of a hip prosthesis (or a natural femoral head) out of the socket.

hip fracture: A break in the upper part of the femur near the hip joint.

internal fixation: Plates, screws, rods or nails placed in surgery to hold a broken bone from inside.

intertrochanteric fracture: A break in the femur between the greater and lesser trochanters, outside the hip joint capsule.

laminectomy: Surgery that removes part of the lamina, the bony arch at the back of a vertebra, to relieve pressure on the spinal cord or nerves.

mechanical lift: A device that raises and moves a person in a sling, from the floor or a ceiling track, so that staff do not bear the person's weight.

neurovascular assessment: A check of blood flow and nerve function in a limb below an injury, cast, splint, bandage or surgical site.

nonunion: A fracture that fails to heal.

open fracture: A fracture in which the bone breaks through the skin or a wound connects with the break, allowing bacteria to reach the bone.

osteomyelitis: Infection of the bone.

osteoporosis: A disease in which bones lose mass and strength and break more easily.

pathologic fracture: A fracture through bone already weakened by disease, such as a tumour that has spread to bone.

periprosthetic joint infection: An infection of an artificial joint and the tissue around it.

phantom limb pain: Pain felt in the part of a limb that has been removed.

pin-site care: The cleaning and dressing of the skin where external fixator or traction pins enter the body.

prehabilitation: Exercise and conditioning before surgery intended to improve recovery afterward.

prosthesis: An artificial device that replaces a missing body part.

reduction: The return of broken bone ends to their normal position, either by hand without an incision (closed) or in surgery (open).

residual limb: The part of a limb that remains after amputation.

safe patient handling: An organized approach that uses assessment, equipment, policy and training to move patients without manual lifting where possible.

secondary fracture prevention: Care that aims to prevent another fracture after a fragility fracture by finding and treating osteoporosis and reducing falls.

spinal fusion: Surgery that joins two or more vertebrae with a bone graft, often held with screws and rods, so that they heal as one bone.

total hip arthroplasty: Surgery that replaces the femoral head and lines the hip socket with artificial parts.

total knee arthroplasty: Surgery that resurfaces the worn ends of the femur and tibia, and often the kneecap, with artificial parts.

traction: A pulling force applied to a limb, through the skin or through a pin in the bone, to restore and keep a broken bone's alignment and length.

Licensure Review & Clinical Judgment Questions (40)

Questions tagged **[Core]** apply to all nursing students (NCLEX-RN, REx-PN, and CPNRE). Questions tagged **[RN]** draw on *Going Deeper* content.

Case: Daniel Kovac (Questions 1–4): Daniel Kovac, 24, fractured the shaft of his left tibia playing hockey and is on an orthopedic unit in Ontario awaiting surgery. His leg is in a long-leg back slab held on with a crepe bandage and is raised on three pillows. At 0200 he tells the RPN that his pain is 9 out of 10 even though he received his ordered opioid one hour ago. He says his leg feels "really tight" and his foot is tingling. His left foot pulse is palpable.

1. [CORE] Which assessment should the RPN complete first?

a. Gently extend Daniel's toes while watching whether stretching the muscles in his lower leg sharply increases his pain.

b. Take his temperature and review his most recent white blood cell count to look for an early wound infection.

c. Reposition him, then ask him to rate his pain again in 30 minutes to see whether the opioid has taken full effect.

d. Recheck his foot pulse with a Doppler device, since a strong pulse means that blood flow to the leg is adequate.

Answer: a — Pain out of proportion to the injury that does not respond to analgesia, with tightness and tingling, suggests compartment syndrome. Pain on passive stretch is one of the earliest and most sensitive signs, so the RPN checks it first (section 33.1, Neurovascular Assessment; section 33.2, Compartment Syndrome). Option b looks for infection, which does not explain these findings in a closed fracture. Option c delays assessment of a possible emergency. Option d is wrong because pulse changes are a late sign; a present pulse does not rule compartment syndrome out.

2. [CORE] Daniel's pain increases sharply when his toes are extended. How should the RPN position his leg while help is called?

a. Add a fourth pillow so that the leg is raised well above the level of his heart to reduce swelling.

b. Remove the extra pillows so that the leg rests at the level of his heart, and keep it supported.

c. Lower the leg over the side of the bed so that gravity can increase blood flow to the foot.

d. Keep the leg on three pillows and place ice packs over the back slab along the length of the calf.

Answer: b — With suspected compartment syndrome, the limb rests at heart level (section 33.2, Compartment Syndrome). Option a raises the limb above the heart, which lowers the pressure driving blood into the compartment and can worsen ischemia. Option c lets the limb hang down and increases swelling. Option d keeps the limb raised and adds nothing to relieve pressure; ice does not treat compartment syndrome.

3. [CORE] Which action should the RPN take next regarding the back slab and bandage?

a. Leave the bandage and back slab untouched until the surgeon arrives, because loosening them could displace the fracture.

b. Rewrap the crepe bandage more firmly over the back slab to hold the fracture still and reduce bleeding into the muscles.

c. Loosen the crepe bandage down to the skin, as policy allows, while keeping the back slab in place to support the leg.

d. Remove the back slab and bandage completely, and leave the leg unsupported on the bed so that it can swell freely.

Answer: c — All circumferential dressings and bandages are released down to the skin when compartment syndrome is suspected; the slab stays in place to support the fracture (section 33.2, Compartment Syndrome). Option a leaves a possible cause of compression in place. Option b adds compression and could make the syndrome worse. Option d removes support from an unstable fracture, which can cause more injury and pain.

4. [CORE] Which action best reflects the RPN's responsibility after loosening the bandage?

a. Document the findings in detail and plan to report them to the surgeon during morning rounds in a few hours.

b. Give the as-needed dose of opioid that is ordered and reassess Daniel's pain and toes in one hour.

c. Ask Daniel to try to rest, and check his neurovascular status again at the next scheduled hourly check.

d. Consult the RN and call the surgeon at once with an SBAR report, then stay with Daniel and reassess.

Answer: d — Compartment syndrome is a surgical emergency, and every nurse who recognizes it notifies urgently and stays with the patient; the RPN consults the RN as the patient's needs change (section 33.2, Compartment Syndrome). Options a and c delay notification. Option b may mask the key sign of rising pain and also delays the call; a rising need for opioids is itself a warning.

5. [CORE] A 67-year-old woman tripped on a rug while walking in her home and broke her wrist. She has no history of cancer. How should the nurse describe this fracture to the team?

a. A pathologic fracture, because the bone was weakened by a disease such as cancer that has spread to bone.

b. An open fracture, because any fracture of the wrist allows bacteria from the skin to reach the bone.

c. A fragility fracture, because a fall from standing height would not usually break a healthy bone.

d. A comminuted fracture, because any fracture from a fall breaks the bone into three or more pieces.

Answer: c — A fragility fracture results from low trauma, such as a fall from standing height, and is a warning sign of osteoporosis (section 33.1, How Bones Break and Heal; section 33.3). Option a describes a break through bone weakened by a disease such as a tumour, which is not suggested here. Option b is wrong because an open fracture requires a wound that connects with the fracture. Option d is wrong because "comminuted" describes the number of pieces, which depends on the injury, not on the fact of a fall.

6. [CORE] A man arrives in the emergency department with an open fracture of the lower leg. The bone ends are visible in a dirty wound. Which action by the nurse is appropriate before he goes to the operating room?

a. Dress the wound with gauze soaked in saline under an occlusive film after it has been photographed.

b. Irrigate the wound thoroughly at the bedside with a large volume of saline to remove all contamination.

c. Leave the wound open to the air so that the surgeon can inspect it at any time without removing a dressing.

d. Push the exposed bone ends gently back under the skin so that the wound can be closed and dressed.

Answer: a — UK open fracture standards call for touching the wound only to clear gross contamination and take photographs, then dressing it with saline-soaked gauze under an occlusive film until surgery (section 33.1, First Care After Injury). Option b is wrong because wound washout is done in the operating room, not at the bedside. Option c leaves the wound exposed to contamination and drying; photographs avoid the need to reopen the dressing. Option d can drive contamination deeper and is never done by the nurse.

7. [CORE] A 52-year-old man with a tibial fracture asks the nurse what he can do to help his bone heal. Which response is most accurate?

a. "Healing depends only on the type of fracture you have, so there is little you can do to change it."

b. "Eating extra calcium every day is the single most important thing you can do to make bones heal faster."

c. "As long as you keep your cast dry, your bone will heal on schedule regardless of other health habits."

d. "Stopping smoking will help, because smoking slows the growth of the new blood vessels the bone needs."

Answer: d — Smoking is linked to higher odds of nonunion and slows the growth of new blood vessels into the healing area (section 33.1, How Bones Break and Heal). Option a is wrong because patient factors such as smoking, diabetes and nutrition also matter. Option b overstates the role of calcium; no single nutrient is described as the most important factor. Option c ignores the patient factors that affect healing.

8. [CORE] The nurse is teaching a patient going home with a new fibreglass forearm cast. Which statement by the patient shows understanding?

a. "If my skin gets itchy under the cast, I'll slide a knitting needle inside to scratch it very gently."

b. "If my fingers turn grey or I can't move them, I'll go to the emergency department right away."

c. "If the cast feels tight tomorrow, I'll trim the top edge with kitchen scissors so it doesn't rub my skin."

d. "I'll sprinkle some baby powder inside the cast every day to keep the skin dry."

Answer: b — Grey or blue fingers, or being unable to move them, can signal compromised circulation or nerve function and need urgent care (section 33.1, Patient Education box). Option a can scrape the skin and lead to infection or pressure injury. Option c is wrong; patients do not cut or trim their casts, and a tight cast needs assessment. Option d is wrong because powders and lotions are not used under a cast.

9. [CORE] The nurse is assessing the foot of a patient with dark skin after surgery to fix an ankle fracture. Which approach gives the most reliable information about circulation?

a. Relying on the colour of the skin of the foot, because pallor is easy to see on all skin tones.

b. Relying on the pedal pulse alone, because a strong pulse rules out any problem with circulation.

c. Asking the patient whether the foot looks normal to them, because they know their own skin best.

d. Checking capillary refill, skin temperature and swelling, and comparing them with the other foot.

Answer: d — Colour alone is not a reliable guide on every skin tone, so the nurse uses capillary refill, temperature, swelling and comparison with the other limb (section 33.1, Neurovascular Assessment). Option a is wrong because skin colour on its own is not a reliable guide to circulation. Option b is wrong because a pulse can be present even when compartment syndrome is developing. Option c may add useful information, but it does not replace a structured assessment by the nurse.

10. [CORE] A patient has a long-leg cast applied for a tibial fracture. Which findings should the nurse report at once? Select all that apply.

a. Numbness and tingling in the toes that were not present an hour ago

b. Pain that keeps rising despite the analgesia that has been given

c. Mild itching under the cast that eases with cool air from a fan

d. Toes that are cool and pale compared with the toes on the other foot

e. Being unable to move the toes when asked to wiggle them

f. Warm, pink toes with capillary refill that matches the other foot

Answer: a, b, d, e — New numbness or tingling, pain that keeps rising despite analgesia, cool and pale toes, and loss of movement are all signs of neurovascular compromise and are reported at once (section 33.1, Table 33.1 and Neurovascular Assessment). Option c is a common, harmless complaint that the patient can manage safely. Option f is an expected finding.

11. [CORE] A patient has an external fixator on the lower leg. Which finding at a pin site suggests infection and should be reported?

a. A small amount of dried, clear crust sealing the edge of the skin around one pin

b. Pin sites that are clean and covered with the dressing applied six days earlier

c. Increasing pain at one pin site with spreading redness and more drainage than before

d. Mild tenderness when the patient first stands, which settles after a few minutes of rest

Answer: c — Increasing pain, spreading redness, more swelling and more drainage are signs of pin-site infection (section 33.1, Casts, Splints and Traction). Option a is common; dried drainage sealing a site is not by itself a sign of infection. Option b fits guidance that supports weekly dressing changes when sites are dry. Option d is a short-lived discomfort without signs of infection.

12. [CORE] A 28-year-old woman is on day two after a fractured femur and pelvis from a car crash. She has become restless and confused, her oxygen saturation has fallen to 88% on room air, and the nurse sees small red spots in her armpits. Which action should the nurse take first?

a. Reorient her and dim the lights, then recheck her mental status in one hour.

b. Apply oxygen per protocol and call for urgent help, such as the rapid response team.

c. Ask the pharmacist whether any of her new medicines could be causing a skin rash and confusion.

d. Encourage her to take deep breaths and use her incentive spirometer every hour.

Answer: b — Falling oxygen saturation, new confusion and petechiae two days after long-bone and pelvic fractures suggest fat embolism syndrome, which needs oxygen and urgent escalation (section 33.2, Fat Embolism Syndrome). Option a treats the confusion as minor and delays care. Option c explores a less likely cause while she is hypoxic. Option d may help breathing in general but does not address a falling saturation with neurologic change.

13. [CORE] Which adult should the nurse expect to be offered bone mineral density testing under the Osteoporosis Canada 2023 guideline?

a. A 66-year-old man whose father broke his hip after a fall in his late seventies.

b. A 55-year-old woman with no previous fractures and no known risk factors for osteoporosis.

c. A 45-year-old man who broke his ankle playing soccer and has no other risk factors.

d. A 60-year-old woman who smokes but has no other risk factors and no fracture history.

Answer: a — The guideline suggests testing at age 65 to 69 with one risk factor, and a parent with a hip fracture is a risk factor (section 33.3, Osteoporosis). Option b has no risk factors and is under 70. Option c is under 50, and a sports injury is not a fragility fracture. Option d is between 50 and 64 with only one risk factor; at that age, testing is suggested only after a previous osteoporosis-related fracture or with at least two risk factors.

14. [CORE] A woman starting alendronate asks how to take it. Which instruction is correct?

a. "Take it at bedtime with a glass of milk so it doesn't upset your stomach overnight."

b. "Take it with breakfast and your calcium pill so you remember to take them together."

c. "Chew the tablet well before swallowing it, then lie down for a few minutes so that it is absorbed."

d. "Take it first thing in the morning with plain water, then stay upright for 30 minutes."

Answer: d — Alendronate is taken first thing in the morning with a full glass of plain water, swallowed whole, and the patient stays upright and lets 30 minutes or more pass before eating, drinking or taking other medicines (section 33.3, Medications box). Option a is wrong because it is never taken at bedtime or with milk. Option b is wrong because food and calcium block absorption. Option c is wrong because the tablet is not chewed and lying down raises the risk of irritating the esophagus.

15. [CORE] A man who has received denosumab for three years tells the nurse he plans to skip his next injection because he feels fine. Which response by the nurse is best?

a. "That's reasonable, because the medicine keeps protecting your bones for years after the last dose."

b. "You could switch to calcium tablets instead, since they work the same way as your injection."

c. "Please talk with your prescriber before stopping, because stopping can cause rapid bone loss."

d. "You can stop safely now, because three years is the usual full course for this medicine."

Answer: c — Stopping or delaying denosumab without a plan is linked to rapid bone loss and spinal fractures, so the patient needs to talk with the prescriber first (section 33.3, Medications box). Option a is wrong because the protective effect fades quickly after stopping. Option b is wrong because calcium does not replace denosumab. Option d gives incorrect information about the course of treatment.

16. [CORE] On an orthopedic unit in Ontario, an RPN who has not cared for a patient with an external fixator is assigned to one. Employer policy allows RPNs to do pin-site care after education. Which action best reflects the College of Nurses of Ontario's (CNO's) approach to scope of practice?

a. Decline the assignment, because only RNs may care for patients with external fixators in Ontario hospitals.

b. Tell the charge nurse about the learning need and complete the education before giving the care.

c. Perform the care using what the RPN remembers from school, since the employer policy allows it.

d. Ask the patient to clean the pin sites, since patients learn the care before they go home anyway.

Answer: b — CNO's approach to scope looks at authority, competence and context; here the employer allows the care, but the RPN must also have the competence, so the RPN speaks up and gets the education first (section 1.3; section 33.1, Casts, Splints and Traction). Option a states a rule that is not part of CNO's standards; who gives this care depends on authority, competence and context, and employer policy allows it here. Option c ignores the need for current competence. Option d hands the nurse's responsibility to the patient before teaching has happened.

17. [CORE] A patient returned from surgery on a forearm fracture two hours ago with a nerve block in the arm. The nurse notes that the fingers are more swollen and cooler than the other hand, but the patient feels no pain. Which action is most appropriate?

a. Report the findings now, because the nerve block can hide the pain of compartment syndrome.

b. Reassure the patient that the absence of pain shows that the circulation in the arm is working normally.

c. Raise the arm on two more pillows above the heart and recheck the fingers at the next scheduled check.

d. Wait until the nerve block wears off so that the patient can report pain before calling the surgeon.

Answer: a — Patients with a nerve block cannot report the pain that is usually the earliest sign of compartment syndrome, so other changes, such as increasing swelling and coolness, need medical review early (section 33.1, Neurovascular Assessment). Option b is wrong because the absence of pain is expected with a block and does not show good circulation. Option c may worsen ischemia if compartment syndrome is developing and delays reporting. Option d delays care until damage may already be done.

18. [RN] A patient with a femoral fracture is in skin traction while waiting for surgery. The nurse finds that the patient has slid down the bed and the weights are resting on the floor. Which action is correct?

a. Lift the weights and tie the rope shorter so that the weights hang just below the end of the bed frame.

b. Remove the weights until the patient's surgery, because traction is no longer needed when it has slipped.

c. Help the patient move up the bed with enough staff so that the weights hang freely again, then check the leg.

d. Leave the weights on the floor, since the pull of traction continues as long as the rope stays in the pulley.

Answer: c — Traction works only when the weights hang freely; the patient is moved up the bed safely so the pull is restored, and the skin and neurovascular status are then checked (section 33.1, Going Deeper: Traction and External Fixation). Option a changes the traction set-up without an order. Option b stops treatment without an order. Option d is wrong because weights resting on the floor exert no pull.

19. [RN] A patient has signs that suggest fat embolism syndrome on day two after a femoral fracture. A student asks how the diagnosis is made. Which response by the nurse is accurate?

a. "A single blood test for fat in the blood confirms the diagnosis and rules out other conditions."

b. "It is a clinical diagnosis, made from the pattern of findings after other causes such as pulmonary embolism are ruled out."

c. "The diagnosis is confirmed only when all three classic signs, including the rash, are present together."

d. "A chest X-ray is the standard test, because it shows the fat droplets lodged in the lung vessels."

Answer: b — Several criteria sets exist, but none has been validated or accepted as a standard; the diagnosis rests on the clinical pattern after other causes are excluded (section 33.2, Fat Embolism Syndrome). Option a is wrong; fat in the blood is common after fractures and does not confirm the syndrome. Option c is wrong because the rash is not seen in every patient, and not all features need to be present. Option d is wrong because a chest X-ray may show changes but does not show fat droplets and does not confirm the diagnosis.

20. [RN] The nurse is teaching new graduates about compartment syndrome. Which statement correctly compares its early and late signs?

a. "Early signs include absent pulses and paralysis, while pain is a late sign that appears only after the nerves are damaged."

b. "Early signs include pale skin and a weak pulse, while pain on passive stretch is a late sign of muscle death."

c. "Early and late signs are the same, so any one finding is enough to rule compartment syndrome in or out."

d. "Pain out of proportion and pain on passive stretch are early signs, while numbness, weakness and absent pulses are late."

Answer: d — Pain out of proportion to the injury and pain on passive stretch are the earliest findings; numbness, weakness, colour change and weak or absent pulses are late (section 33.2, Compartment Syndrome). Options a and b reverse the order of the signs. Option c is wrong because the signs differ in timing and no single finding rules the condition out; a present pulse, for example, does not exclude it.

Case: Edna Kowalczyk (Questions 21–26): Edna Kowalczyk, 86, had a hemiarthroplasty yesterday afternoon for a displaced femoral neck fracture after a fall at home, where she lived alone and walked with a cane. On admission she was alert and oriented and wore glasses and hearing aids. At 0300 the nurse finds her trying to climb out of bed and pulling at her IV. She says she must get home to feed her children, cannot keep track of the nurse's questions, and dozes between answers. Vital signs: temperature 37.4 °C, heart rate 104, respiratory rate 22, blood pressure 108/62 mm Hg and oxygen saturation 91% on room air (96% at 2000). She has no urinary catheter and has voided 120 mL since 2000. Her hemoglobin at 1800 yesterday was 84 g/L (112 g/L before surgery). She grimaces when her leg is moved; her last opioid dose was at 1800, and she declined a dose at 2200. Her glasses and hearing aids are in the bedside drawer.

21. [CORE] Which findings at 0300 should the nurse recognize as cues that need follow-up? Select all that apply.

a. New confusion with inattention and drowsiness
b. Oxygen saturation of 91% on room air
c. Urine output of 120 mL since 2000
d. Temperature of 37.4 °C
e. Heart rate of 104
f. Lived alone and walked with a cane before the fall
g. Hemoglobin of 84 g/L, down from 112 g/L

Answer: a, b, c, e, g — Confusion that began suddenly, with inattention and drowsiness, is a cue for delirium (a; section 33.4; Chapter 8). A fall in saturation from 96% to 91% suggests hypoxemia (b). An output of 120 mL over 7 hours is low and may mean low volume or urinary retention (c). A heart rate of 104 may reflect pain, hypoxemia, low volume or bleeding (e). A hemoglobin drop to 84 g/L reflects surgical blood loss and needs watching with her other findings (g). A temperature of 37.4 °C is within a normal range on day 1 after surgery (d). Her living situation and cane use are background for discharge planning, not a change that needs follow-up tonight (f).

22. [CORE] Which explanation best links Mrs. Kowalczyk's findings?

a. She has dementia that was missed before surgery, and the unfamiliar hospital setting at night is now making it visible to staff.
b. She is having a normal reaction to anesthesia that will pass on its own within a few hours without any treatment.
c. She has delirium, likely with several causes, including low oxygen, untreated pain, low urine output and blood loss.
d. She is anxious about her children and her home, and anxiety explains her fast heart rate, breathing and low output.

Answer: c — Her confusion began suddenly, fluctuates and comes with inattention and drowsiness, which fits delirium (c; section 33.4; Chapter 8). Hypoxemia, pain, possible urinary retention or low volume, and anemia are all possible contributors. She was oriented on admission, so a long-standing dementia does not explain a sudden change (a). Anesthetic effects do not explain new findings at 0300 on day 1, and delirium needs a search for causes (b). Anxiety does not cause a falling saturation or low urine output (d).

23. [RN] Which concern should the nurse treat as the priority?

a. Possible hypoxemia with a fast heart rate after surgery, which could signal pulmonary embolism, pneumonia or bleeding and needs urgent assessment.
b. Constipation from opioids and bed rest, which can cause restlessness in older adults and needs a bowel routine started in the morning.
c. Disturbed sleep in a noisy unit, which is common after surgery and needs a quiet room and fewer checks overnight to let her rest.
d. Risk of a fall from climbing out of bed, which needs a bed alarm and a sitter so that she cannot leave the bed before the morning.

Answer: a — A falling saturation with a fast heart rate threatens oxygen delivery to the brain and heart, and causes such as pulmonary embolism, pneumonia or bleeding can become life-threatening, so this comes first (a; sections 33.4 and 33.5; Chapters 6 and 15). Constipation does not explain hypoxemia (b). Fewer checks would be unsafe while she is unstable (c). Fall prevention matters, but it does not address the cause of her change (d).

24. [CORE] Which plan best addresses the likely causes of Mrs. Kowalczyk's delirium?

a. Ask the physician for an order for wrist restraints and a sedative so that she stays in bed and keeps her IV in place until morning.
b. Apply oxygen per protocol, treat her pain, check her bladder with a scanner as ordered, and give back her glasses and hearing aids.
c. Hold all further opioid doses, since opioids cause confusion, and reassess her thinking after she has slept for the rest of the night.
d. Move her to a bed near the nursing station, dim the lights, and recheck her vital signs and saturation at the next scheduled time.

Answer: b — Oxygen, pain control, finding and treating urinary retention and restoring her glasses and hearing aids each address a likely cause of delirium (b; section 33.4; Chapter 8). Restraints and sedatives can worsen delirium and are not first-line (a). Untreated pain also causes delirium, so holding all analgesia is not the answer; the team chooses the analgesic approach (c; Chapter 5). Waiting for the next scheduled check delays action for an unstable patient (d).

25. [CORE] The nurse calls the on-call surgical resident. Which report best follows SBAR?

a. "Mrs. Kowalczyk in room 12 is very confused and pulling at her IV, and we cannot keep her in bed. Can you order something to calm her down?"

b. "I'm calling about Mrs. Kowalczyk, day 1 after hemiarthroplasty. Her vitals are a bit off and she is confused. Could you come and see her when you get a chance?"

c. "Mrs. Kowalczyk's hemoglobin was 84 last evening. Should we transfuse? She also seems confused, but her daughter said she gets mixed up at night."

d. "Mrs. Kowalczyk, 86, day 1 after hemiarthroplasty, has new confusion and a saturation of 91%, down from 96%. Heart rate 104, hemoglobin 84 from 112, output 120 mL since 2000. I think she has delirium with hypoxemia. Please come now."

Answer: d — Option d gives the situation, background, assessment with specific numbers and the nurse's interpretation, and a clear request, which is the SBAR structure (d; section 33.4; Chapter 6). Option a asks for sedation without data or a search for causes (a). Option b is vague and does not state urgency (b). Option c focuses on the hemoglobin, includes unverified information and leaves out the hypoxemia (c).

26. [CORE] By 1000, Mrs. Kowalczyk is on oxygen and her pain is treated. Which finding best shows that her plan of care is working?

a. She is sleeping soundly with bed rails up, and she has not tried to get out of bed since the sedative given at 0400.

b. Her daughter has asked to take her home today, and the team has agreed to discharge her without further assessment.

c. She answers attention questions correctly, has a saturation of 95%, and has sat at the bedside and walked a few steps with the physiotherapist.

d. Her hemoglobin is unchanged at 84 g/L, and she has been kept in bed so that her new hip can rest until she is less confused.

Answer: c — Improved attention, better oxygenation and mobilization on day 1 show that delirium is clearing and recovery is on track (c; section 33.4). Sleeping after a sedative does not show that delirium has resolved and may hide it (a). Discharge on day 1 without assessment is unsafe and does not measure her response (b). Keeping her in bed works against the standard's goal of weight bearing within 24 hours, and her family can help by sitting with her, reorienting her and joining her walks (d).

27. [CORE] An 81-year-old man with a hip fracture arrived at a small rural hospital at 0800 on Monday and was transferred to a regional centre, arriving at 1600 on Monday. According to the Ontario hip fracture quality standard, by what time should his surgery take place?

a. By 0800 on Wednesday, 48 hours after he first arrived at the rural hospital

b. By 1600 on Wednesday, 48 hours after he arrived at the regional centre

c. By 1600 on Tuesday, 24 hours after he arrived at the regional centre

d. Within 48 hours of the time the orthopedic surgeon first assessed him at the centre

Answer: a — The standard starts the 48-hour clock when the person first arrives at any hospital, so time at a hospital that does not do the surgery counts (a; section 33.4). Starting the clock at the regional centre or at the surgeon's assessment would hide the delay caused by transfer (b, d). The standard's target is 48 hours, not 24 (c).

28. [CORE] On the first day after surgery for a hip fracture, a 79-year-old woman tells the nurse, "I'll just stay in bed until the pain is gone." Her surgeon has ordered weight bearing as tolerated. What is the nurse's best response?

a. "That's fine. Your hip needs a few days of rest so the bone can heal before you put any weight through it."

b. "Getting up today, with your pain treated first, lowers your risk of complications and helps you get home sooner."

c. "You'll need to walk the full length of the hall today, even if it hurts, or you won't be able to go home."

d. "Let's wait until the physiotherapist comes tomorrow, and they can decide whether you are ready to get out of bed."

Answer: b — The quality standard calls for weight bearing as tolerated in the first 24 hours after surgery and daily mobilization, with pain treated so that the person can move (b; section 33.4). Bed rest increases complications and delays recovery (a). Forcing a long walk through pain is unsafe and unkind (c). Nurses mobilize patients as ordered, and waiting a day delays care (d).

29. [CORE] A 74-year-old woman is recovering from surgery for a fragility hip fracture. Which action best supports secondary fracture prevention before she leaves hospital?

a. Teach her to avoid walking outdoors for the next year so that she does not fall on uneven ground.

b. Tell her to ask her family physician about a bone density test and treatment at her next routine visit next year.

c. Arrange a fracture risk assessment in hospital and an offer of osteoporosis treatment when appropriate.

d. Advise her to take a high dose of calcium each day, since that alone will prevent another fracture.

Answer: c — The standard calls for a clinician with expertise in osteoporosis to assess fracture risk in hospital and for osteoporosis medicine to be offered when appropriate (c; sections 33.3 and 33.4). Avoiding walking leads to weakness and more falls (a). Leaving assessment for a later visit misses the chance to act (b). Calcium alone does not prevent fractures, and doses follow the guideline (d; section 33.3).

30. [CORE] A man is to have a posterior-approach total hip arthroplasty. He asks whether he will have to follow "hip rules" for life, as his neighbour did. What is the nurse's best response?

a. "Everyone who has a hip replacement must follow the same set of hip rules for the rest of their life to avoid dislocation."

b. "Hip rules are no longer used anywhere, so you can move any way you like as soon as you wake up from surgery."

c. "You should follow your neighbour's rules, because they worked for him and his surgery was done the same way."

d. "Practice varies, and recent evidence questions routine rules. Follow the instructions your own surgeon gives you."

Answer: d — A 2023 meta-analysis found that routine hip precautions after posterior-approach THA may make little or no difference to early dislocation, and practice varies, so the patient follows his surgeon's protocol (d; section 33.5). There is no single lifelong rule for everyone (a). Some surgeons still order precautions, so saying they are never used is wrong (b). Another person's rules may not apply (c).

31. [CORE] The nurse is teaching a patient going home after a total knee arthroplasty. Which findings should the patient report promptly? Select all that apply.

a. Redness, warmth and new drainage from the incision
b. New pain and swelling in the calf
c. Mild stiffness in the knee after sitting for an hour
d. Sudden shortness of breath or chest pain
e. Fever with knee pain that keeps getting worse
f. Bruising around the knee that is fading

Answer: a, b, d, e — Redness, warmth, drainage, fever and increasing pain may signal infection, including a periprosthetic joint infection (a, e; section 33.5). Calf pain and swelling may signal deep vein thrombosis, and sudden shortness of breath or chest pain may signal pulmonary embolism (b, d; Chapters 15 and 19). Mild stiffness after sitting and fading bruising are expected during recovery (c, f).

32. [CORE] Four hours after a lumbar laminectomy, a patient tells the RPN that her left foot "feels numb and won't lift properly." Her preoperative baseline showed full strength and normal sensation in both legs. What should the RPN do first?

a. Reposition her on her side, since numbness is usually caused by lying on the back for too long.
b. Recheck the finding at the next scheduled assessment in 4 hours and document the change.
c. Give her ordered analgesic, since pain can make it hard to lift the foot after spine surgery.
d. Compare both legs with the baseline and report the change to the RN and surgeon at once.

Answer: d — New weakness or numbness after spine surgery may signal bleeding or swelling pressing on the nerves, such as an epidural hematoma, so the RPN confirms the change against the baseline and escalates at once (d; section 33.5; Chapter 6). Assuming a position cause or waiting delays care (a, b). Analgesia does not address a new neurologic deficit (c).

33. [CORE] Six hours after spinal fusion, a patient whose urinary catheter was removed in the recovery room has not voided and says his lower abdomen feels full. What should the nurse do next?

a. Encourage him to drink more fluids and recheck in 4 hours, since he is probably dehydrated.
b. Assess his bladder with a scanner as ordered and report retention to the prescriber.
c. Insert a urinary catheter and leave it in place for the rest of his hospital stay.
d. Tell him that this is expected after spine surgery and that he will void in time.

Answer: b — Urinary retention is common after spine surgery, and the ERAS guideline advises checking that the bladder empties after catheter removal (b; section 33.5). More fluid could worsen an already full bladder (a). Catheterization follows orders, and leaving a catheter in raises infection risk (c). A full bladder with discomfort needs action, not reassurance (d).

34. [CORE] A patient had an above-knee amputation 2 days ago. Which nursing action best helps prevent a hip flexion contracture?

a. Keep a pillow under the residual limb at all times to reduce swelling and pain.
b. Keep the head of the bed raised high so that he is sitting up most of the day.
c. Help him lie prone or flat for periods as ordered and avoid propping the limb.
d. Have him rest in a chair with the hip bent for most of the day to build tolerance.

Answer: c — Lying flat or prone and keeping the hip straight stretch the hip flexors and help prevent a contracture that would make a prosthesis hard to fit (c; section 33.6). Pillows under the limb, a high head of bed and long periods sitting all keep the hip bent (a, b, d).

35. [CORE] Three days after a below-knee amputation, a patient says, "My missing foot is burning. I must be going crazy." What is the nurse's best response?

a. "Phantom pain is common and real. Tell me more about it so we can treat it with the team."
b. "Your foot has been removed, so the pain must be coming from somewhere else in your leg."
c. "Try to think about something else, and the feeling will go away once you stop focusing on it."
d. "That feeling usually means the incision is infected, so I will ask the surgeon to see you."

Answer: a — Phantom limb pain is pain felt in the removed part of the limb; it affects about 64% of people with amputation and needs assessment and treatment (a; section 33.6; Chapter 5). Dismissing it or blaming the person's thinking is inaccurate and unhelpful (b, c). Phantom pain is not a sign of infection (d).

36. [CORE] A 58-year-old First Nations man from a remote fly-in community is recovering from a below-knee amputation related to diabetes and PAD. Which nursing action best reflects culturally safe care?

a. Plan his care as for any patient, since his background does not affect his recovery after amputation.
b. Tell him that his amputation was caused by not managing his diabetes well and that he must do better.
c. Arrange discharge to a city rehabilitation centre without discussing it, since his community lacks services.
d. Ask about his goals and supports, and plan with him, his family and his community's health services.

Answer: d — Culturally safe, strengths-based care plans with the person, family and community services, and recognizes structural barriers such as distance and limited wound care and rehabilitation services (d; section 33.6; Chapter 2). Ignoring his context can create gaps at discharge (a). Blaming the person ignores the structural causes of higher amputation rates (b). Decisions are made with him, not for him (c).

37. [CORE] A patient on day 2 after a hip fracture repair is newly confused, cannot follow directions and cannot bear weight today, although yesterday she stood with one assist. She needs to move from the bed to a chair. What is the safest approach?

a. Reassess, update the mobility plan, and use a full mechanical lift with the staff that policy requires.

b. Ask two staff to lift her under the arms and swing her into the chair quickly.

c. Stand and pivot her with one nurse using a transfer belt, as the mobility plan said yesterday.

d. Leave her in bed for the day, since moving her while she is confused is never safe.

Answer: a — The nurse reassesses before every move. A person who cannot follow directions or bear weight needs a full mechanical lift, and the plan is updated (a; section 33.7). Manual lifting injures staff and patients (b). Yesterday's plan no longer fits (c). Staying in bed adds risk; safe equipment allows movement (d).

38. [CORE] An RPN new to an orthopedic unit is asked to transfer a patient with a ceiling lift. She has never been trained on this model. What should the RPN do?

a. Use the lift anyway, since all lifts work the same way and the patient is waiting.

b. Ask for training or for a trained colleague to help before she uses the lift.

c. Move the patient manually with help, since that is faster than learning the lift.

d. Refuse to move the patient and document that the transfer was not possible.

Answer: b — Competence is one of CNO's three considerations: a nurse who has not been trained in a skill gets education or help before doing it (b; section 33.7; Chapter 1, section 1.3). Using unfamiliar equipment risks injury (a). Manual lifting is unsafe (c). The patient still needs to move, so the RPN finds a safe way to help (d).

39. [RN] On the first day after a posterior-approach total hip arthroplasty, a patient bends forward to pick up his slipper and cries out. His leg now looks shorter and turned inward, and he cannot move it. What should the nurse do?

a. Keep him still, check circulation and sensation in his foot, and notify the surgeon at once.

b. Help him back into bed and gently straighten his leg to see whether the hip moves back into place.

c. Give his ordered analgesic, apply ice, and reassess his hip and leg position in 1 hour.

d. Have him stand with a walker to check whether he can bear weight on the operated leg.

Answer: a — Sudden pain with a shortened, rotated leg after a movement suggests a hip dislocation. The nurse keeps the person still, checks the limb's circulation and sensation, and notifies the surgeon at once (a; section 33.5). Moving the leg can injure nerves and vessels (b). Analgesia matters, but waiting delays reduction (c). Standing on a dislocated hip is unsafe (d).

40. [RN] Which patient's hemoglobin result most clearly needs a prompt report to the prescriber for a transfusion decision?

a. Day 2 after a hip fracture repair, hemoglobin 86 g/L, no symptoms, walking with a walker

b. Day 1 after total knee arthroplasty, hemoglobin 98 g/L, mild incision pain, vital signs at baseline

c. Day 3 after a hip fracture repair, hemoglobin 82 g/L, no symptoms, eating and sleeping well

d. Day 2 after hemiarthroplasty, hemoglobin 74 g/L, dizzy on standing, heart rate 112, new chest discomfort

Answer: d — The Ontario hip fracture standard advises against transfusion for people without symptoms whose postoperative hemoglobin is at least 80 g/L, and the AABB guideline suggests considering transfusion below 70 g/L for most stable adults, or below 80 g/L after orthopedic surgery or with cardiovascular disease (d; section 33.5; Chapter 20). A hemoglobin of 74 g/L with dizziness, tachycardia and chest discomfort needs a prompt report. The other three patients have no symptoms and a hemoglobin above 80 g/L, so they are monitored (a, b, c).

34 Arthritis and Connective Tissue Disorders

LEARNING OUTCOMES & COMPETENCY MAPPING

By the end of this chapter, you will be able to:

1. Assess an adult with joint symptoms, including inflammatory signs on a range of skin tones, and recognize a hot joint as urgent.
2. Support adults with osteoarthritis through exercise, self-management and safe use of pain medicines.
3. Explain rheumatoid arthritis and its treat-to-target care, and teach safe use of methotrexate as a once-weekly medicine.
4. Care for adults with gout during and between flares, including teaching about urate-lowering therapy.
5. Recognize flares and organ involvement in lupus, and recognize giant cell arteritis as an emergency, using the CJMM.
6. Give safe care to adults taking disease-modifying drugs, biologics, JAK inhibitors and corticosteroids, including screening, infection risk and access.
7. Distinguish RN and RPN roles in arthritis care using CNO's authority, competence and context.

How the outcomes map to the CNO entry-to-practice competencies

Outcome	RN competency role (CNO, 2019a)	RPN competency category (CNO, 2019b)
1, 2, 3, 4, 5	Clinician; Educator	Foundations of Practice
6	Clinician; Advocate	Foundations of Practice; Ethical Practice
7	Professional; Collaborator	Legal Practice; Collaborative Practice

Introduction

Arthritis is one of the most common reasons adults in Canada live with pain and limited movement. Arthritis Society Canada (n.d.-a) reports that about 6 million people, or 1 in 5 adults, have arthritis, and that half of them are younger than 65. Nurses meet these patients in every setting: a man with knee osteoarthritis admitted with pneumonia, a woman with rheumatoid arthritis whose weekly medicine must continue safely after surgery, an older adult whose joints keep them from getting out of bed. Arthritis is often not the reason for admission, but it shapes how a person moves, sleeps, works and copes, and the medicines used to treat it carry real risks.

This chapter is the book's home for arthritis and connective tissue disorders in adults. Section 34.1 reviews how joints work, how nurses assess joint symptoms and what arthritis looks like in Canada. Section 34.2 covers osteoarthritis, and section 34.3 covers rheumatoid arthritis, including the safe use of methotrexate as a once-weekly medicine. The second half of the chapter covers gout (34.4), systemic lupus erythematosus and other connective tissue disorders (34.5), medicines for inflammatory arthritis (34.6) and living well with chronic arthritis (34.7).

The chapter builds on earlier ones. Scope of practice for registered nurses (RNs) and registered practical nurses (RPNs) is taught in section 1.3, and the Clinical Judgment Measurement Model (CJMM) in section 1.4. Outside Ontario, practical nurses (PNs) are often called licensed practical nurses (LPNs); this chapter uses "the nurse" unless the roles differ. Inflammation and infection are covered in Chapter 4, pain and multimodal analgesia in Chapter 5, and recognizing deterioration and reporting with SBAR (Situation, Background, Assessment, Recommendation) in Chapter 6. Older adults and their medicines are in Chapter 8, the immune system in Chapter 21, kidney disease in Chapter 27, and osteoporosis and joint replacement in Chapter 33. Cultural safety and Indigenous health are in Chapter 2.

34.1 Joints, Inflammation and Arthritis in Canada

How Joints Work

Most joints that move freely, such as the knees, hips, shoulders and fingers, are **synovial joints**. In a synovial joint, the ends of two bones are capped with smooth **articular cartilage**, a firm, slippery tissue that lets the bones glide and spreads the load across the joint. A fibrous capsule encloses the joint. Its inner lining, the **synovium** (synovial membrane), makes a small amount of thick synovial fluid that lubricates the joint and nourishes the cartilage, which has no blood supply of its own. Ligaments, tendons and the muscles that cross the joint hold it steady (Figure 34.1).

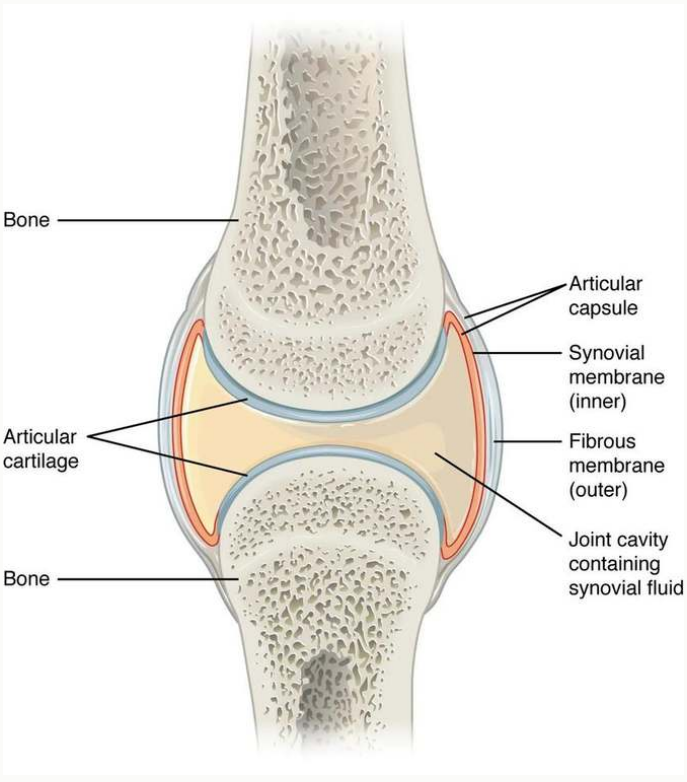

Figure 34.1 Structure of a synovial joint, showing the articulating bones, hyaline articular cartilage, joint cavity containing synovial fluid, and the articular capsule composed of an outer fibrous membrane and an inner synovial membrane. (credit: "Figure 9.8, Synovial Joints" by J. Gordon Betts et al./OpenStax, Anatomy and Physiology 2e, CC BY-NC-SA 4.0)

Inflammation is the body's response to injury, infection or an immune attack. Blood vessels widen, fluid and immune cells move into the tissue, and the area becomes warm, swollen, painful and harder to use (section 4.1). In a joint, the inflamed synovium thickens and makes extra fluid, so the joint swells and may feel soft or boggy. Short-lived inflammation settles once the cause is removed. Inflammation that continues for months, as in untreated rheumatoid arthritis, can wear away cartilage and bone and loosen the tissues that hold the joint steady.

Arthritis literally means inflammation of a joint, but the word covers many conditions that affect joints and the tissues around them. Nurses find it helpful to sort them into two broad groups. In **non-inflammatory arthritis**, mainly osteoarthritis, the joint wears down because the body's repair processes cannot keep up with tissue damage (Arthritis Society Canada, n.d.-b). In **inflammatory arthritis**, the immune system or crystals inflame the synovium, a process called **synovitis**. Rheumatoid arthritis is an **autoimmune disease**: the immune system attacks the body's own tissue, in this case the lining of the joints (Arthritis Society Canada, n.d.-c). Gout is a crystal arthritis (section 34.4). Some inflammatory diseases, such as lupus, also affect the skin, kidneys and other organs (section 34.5).

The difference matters. Inflammatory arthritis can damage joints. In rheumatoid arthritis, for example, people who are diagnosed and treated early are less likely to have long-term joint damage and loss of function (Public Health Agency of Canada [PHAC], 2020c). Damaged joints generally cannot be repaired except by surgery (Arthritis Society Canada, n.d.-c).

Assessing the Person With Joint Symptoms

The nurse starts with the person's story. Useful questions include:

- **Onset and pattern:** Did symptoms begin suddenly or over months? Is one joint involved, a few or many? Are the same joints affected on both sides of the body?
- **Morning stiffness:** How long does stiffness last after getting up? Stiffness from osteoarthritis usually eases in less than 30 minutes (Arthritis Society Canada, n.d.-b), whereas **morning stiffness** that lasts 30 minutes or longer is one warning sign of rheumatoid arthritis (Arthritis Society Canada, n.d.-c).
- **Pain:** Is it worse with use and better with rest, or worst after rest? Pain assessment tools are in section 5.2.

- **Whole-body symptoms:** Fatigue, low-grade fever, weight loss and poor appetite can come with rheumatoid arthritis (Arthritis Society Canada, n.d.-c). A rash, mouth ulcers or chest pain that is worse with breathing points toward a connective tissue disorder (section 34.5).
- **Function:** What has become hard to do: dressing, opening jars, climbing stairs, working, caring for others?
- **Background:** Past joint injury, family history, smoking, other conditions and all medicines, including over-the-counter anti-inflammatory drugs.

On examination, the nurse looks at each joint and compares it with the same joint on the other side. Swelling, loss of the normal joint outline, deformity and firm lumps under the skin are noted. The nurse gently feels for warmth, tenderness and soft swelling, checks how far the person can move the joint, listens or feels for grinding (crepitus), and watches the person walk and use their hands.

Function deserves the same care as the joints themselves. The nurse watches the person rise from a chair, walk, reach and grip, and asks about self-care, household tasks, work, sleep and the activities that matter most to them, such as gardening, playing with grandchildren or getting to ceremony or church. These findings set a baseline for judging whether treatment is working and guide referrals to physiotherapy and occupational therapy.

Redness can be hard to see on darker skin tones, so the nurse does not rely on colour alone and also checks for warmth, swelling and tenderness, which can be assessed on every skin tone. The nurse compares warmth over the joint with the same spot on the other side using the back of the hand, and asks the person whether the joint looks or feels different from usual. Skin assessment on a range of skin tones is taught in Chapter 35.

A **red flag** is a finding that needs prompt action. A single hot, swollen joint that has become painful and hard to move over a short time is treated as **septic arthritis** (infection inside the joint) until proven otherwise, even if the person has no fever (Weston & Coakley, 2006). This UK guideline also advises that joint fluid be drawn off (aspirated) before antibiotics are started (Weston & Coakley, 2006). The nurse therefore reports the finding to the prescriber at once and watches for signs of sepsis (section 4.6), escalating immediately if they appear. Other red flags in this chapter include a new headache with jaw pain in an older adult (section 34.5) and fever or a new cough in a person taking methotrexate (section 34.3).

CANADIAN CONTEXT

Arthritis in Canada

- **How common:** About 6 million people in Canada, or 1 in 5 adults, report arthritis. It is more common among people assigned female at birth (1 in 4) than male at birth (1 in 6), and the number is expected to grow by 50% by 2045 (Arthritis Society Canada, n.d.-a). These survey figures leave out people living on reserves and in the territories.
- **Diagnosed disease:** In 2016–2017, about 3.9 million Canadians aged 20 and older (13.6%) lived with diagnosed osteoarthritis (PHAC, 2020b), and about 374,000 aged 16 and older (1.2%) lived with diagnosed rheumatoid arthritis (PHAC, 2020c). These counts come from the Canadian Chronic Disease Surveillance System (CCDSS), which uses physician and hospital records.
- **Daily life:** More than 40% of people with arthritis have pain that limits their activities (Arthritis Society Canada, n.d.-a).
- **First Nations:** In an Alberta population study, rheumatoid arthritis affected about three times as many First Nations residents as non–First Nations residents. First Nations patients with rheumatoid arthritis had more primary care visits but fewer specialist visits (Barnabe et al., 2017). This book follows the First Nations principles of OCAP® (ownership, control, access and possession), under which First Nations govern how data about them are collected and used (Chapter 2). Structural causes, including the ongoing effects of colonization, racism in health care and distance from specialist care, shape these gaps (Chapter 2).
- **Rural and remote:** People far from a rheumatology clinic may travel long distances for care; telephone and virtual follow-up are discussed in section 34.7.

GOING DEEPER

Blood Tests and Joint Fluid in Arthritis

Required for RN students; optional for PN students.

No single blood test diagnoses arthritis. Results are read alongside the history and examination, and reference ranges vary by laboratory.

- **C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR):** Both rise with inflammation from any cause, including infection. They support a diagnosis of inflammatory arthritis but are not specific (Jung & Barra, 2015).
- **Rheumatoid factor (RF) and anti-CCP antibodies:** RF also appears in other conditions, such as hepatitis C and bacterial endocarditis. Antibodies to cyclic citrullinated peptides (anti-CCP) are more specific for rheumatoid arthritis: in one Canadian review, specificity was 96% for anti-CCP compared with 86% for RF (Jung & Barra, 2015). Many people with rheumatoid arthritis test negative for both, so a negative result does not rule it out (Arthritis Society Canada, n.d.-c; Jung & Barra, 2015). The 2010 American College of Rheumatology (ACR) and European Alliance of Associations for Rheumatology (EULAR) classification criteria combine joint count, these antibodies, CRP or ESR and symptom duration (Jung & Barra, 2015).
- **Antinuclear antibodies (ANA):** A positive ANA is the entry requirement of the 2019 EULAR/ACR classification criteria for systemic lupus erythematosus (Aringer et al., 2019); see section 34.5.
- **Serum urate:** Reported in µmol/L; used mainly in gout (section 34.4).
- **Joint fluid:** Fluid aspirated from a swollen joint can be tested for infection and examined for crystals: uric acid crystals in gout, or calcium pyrophosphate crystals in pseudogout (PHAC, 2020a). When infection is possible, aspiration comes before antibiotics (Weston & Coakley, 2006).

34.2 Osteoarthritis

What Happens in Osteoarthritis

Osteoarthritis (OA) is the form of arthritis that people in Canada have most often (Arthritis Society Canada, n.d.-b; PHAC, 2020b). It is a progressive disease of the whole joint. The cartilage and the bone underneath it slowly break down when the joint's repair processes cannot keep pace with damage (Arthritis Society Canada, n.d.-b). As cartilage thins, the joint space narrows, the bone ends change shape and the joint becomes stiff and painful. OA most often affects the knees, hips, big toes, hands and spine (Arthritis Society Canada, n.d.-b; Figure 34.2).

Figure 34.2 Bony enlargements at the distal interphalangeal joints (Heberden nodes) in hand osteoarthritis. (credit: “Heberden-Arthrose” by Drahreg01/Wikimedia Commons, CC BY-SA 3.0)

OA is common and becoming more so. In 2016–2017, about 3.9 million Canadians aged 20 and older lived with diagnosed OA, and about 219,000 were newly diagnosed that year. Prevalence was higher among females (16.1%) than males (11.1%), and both prevalence and new diagnoses rise with age (PHAC, 2020b). OA is not only a disease of old age: nearly one third of people with OA in Canada were diagnosed before age 45 (Arthritis Society Canada, n.d.-a).

Arthritis Society Canada (n.d.-b) lists these risk factors:

- older age, female sex and family history;
- excess body weight;
- a previous joint injury, or repeated stress on a joint from work or sport;
- a joint that formed abnormally, or weak muscles around the joint;
- a sedentary lifestyle.

Symptoms usually build over months or years and often come and go at first. Heavy use typically makes the pain worse, and rest eases it; as OA advances, pain can come with ordinary activity, at rest and at night. Morning stiffness is usually brief, lasting less than 30 minutes. The person may notice less movement, swelling, grinding or creaking, and a feeling that the joint is unstable. OA

Figure 34.3 Anteroposterior X-ray of the left knee showing features of osteoarthritis: joint-space narrowing, increased density of the bone beneath the cartilage and marginal osteophytes (bone spurs). (credit: "Osteoarthritis on X-ray" by James Heilman, MD/Wikimedia Commons, CC BY-SA 4.0)

also reaches beyond the joint: poor sleep, low mood, fatigue and **pain sensitization**, in which the nervous system amplifies pain signals, are common (Arthritis Society Canada, n.d.-b). Pain physiology and sensitization are taught in section 5.1.

There is no single test for OA. The diagnosis rests on symptoms and a physical examination. When a person over 40 has typical symptoms, imaging is usually not needed unless an injury must be ruled out, treatment is not working or surgery is being planned, and what an X-ray shows does not always match how the joint feels (Arthritis Society Canada, n.d.-b). Table 34.1 compares OA with rheumatoid arthritis (Figure 34.3).

Table 34.1 Osteoarthritis and rheumatoid arthritis compared (Arthritis Society Canada, n.d.-b, n.d.-c; PHAC, 2020b, 2020c)

Feature	Osteoarthritis	Rheumatoid arthritis
Main process	Breakdown of cartilage and underlying bone when repair cannot keep up with damage	Autoimmune inflammation of the joint lining (synovitis)
Diagnosed cases in Canada, 2016–2017	About 3.9 million adults aged 20 and older (13.6%)	About 374,000 people aged 16 and older (1.2%)
Usual onset	Gradual, over months to years; more common with age	Over weeks to months; often begins between ages 40 and 60
Joints usually affected	Knees, hips, big toes, hands and spine; often one side more than the other	Small joints of the hands, wrists and feet, as well as larger joints; usually the same joints on both sides
Morning stiffness	Usually less than 30 minutes	30 minutes or more
Whole-body effects	Poor sleep, low mood and fatigue linked to pain	Fatigue, low-grade fever, weight loss; can affect the eyes, lungs, heart, skin and nerves
Blood tests	No blood test diagnoses it	Inflammation markers often raised; RF or anti-CCP may be positive
Main treatment	Education, exercise and weight management; topical or oral medicines as needed	Early disease-modifying drugs aimed at remission, plus self-management

Care and Self-Management

The Osteoarthritis Research Society International (OARSI) guideline for knee, hip and polyarticular (many-joint) OA names **core treatments** for everyone with OA: education about arthritis and a structured, land-based exercise program. For knee OA, the core treatments also include mind–body exercise such as tai chi or yoga, and the exercise program may be combined with dietary weight management (Bannuru et al., 2019). Arthritis Society Canada (n.d.-b) gives the same message: movement, not rest, protects the joint. Strengthening, range-of-motion, endurance and balance exercises all help, and low-impact activities such as walking, cycling and water exercise are good choices. The long-term goal for adults is 150 minutes of moderate to vigorous activity a week, built up gradually. For people carrying extra weight, a loss of about one tenth of body weight can ease knee strain and pain (Arthritis Society Canada, n.d.-b).

Physiotherapists and occupational therapists design exercise programs and recommend walking aids, braces, splints, orthotics and changes at home or work (Arthritis Society Canada, n.d.-b). The nurse reinforces the program, checks that a cane or walker is the right height and is used correctly, and asks what makes exercise hard: pain, fear of damaging the joint, cost or lack of a safe place to walk in winter.

Medicines support, but do not replace, exercise and weight management. The OARSI guideline ranks them by the person's other health conditions (Bannuru et al., 2019):

- **Topical NSAIDs:** A **nonsteroidal anti-inflammatory drug (NSAID)** applied to the skin is strongly recommended for knee OA, including for people with gastrointestinal or cardiovascular conditions or frailty. Only a small amount reaches the blood: the Canadian monograph for one over-the-counter diclofenac gel, which is labelled for recent muscle and joint injuries, reports that about 6% of the applied dose is absorbed and warns against using it with oral NSAIDs (Haleon Canada ULC, 2026).
- **Oral NSAIDs:** Oral NSAIDs, such as naproxen and ibuprofen, or a cyclooxygenase-2 (COX-2) inhibitor such as celecoxib, are conditionally recommended for people without other major conditions. For people with stomach or bowel conditions, the guideline favours a COX-2 inhibitor, or a non-selective NSAID taken with a medicine that protects the stomach. Oral NSAIDs are not recommended for people with cardiovascular disease or frailty (Bannuru et al., 2019).
- **Acetaminophen:** The OARSI panel conditionally advised against acetaminophen for OA because it showed little or no benefit and a possible signal of liver harm (Bannuru et al., 2019). Arthritis Society Canada (n.d.-b) still lists it among the options a person can discuss with a prescriber or pharmacist. When it is used, the nurse counts every source toward the daily limit (section 5.3).
- **Duloxetine:** This antidepressant is an option for knee OA in people who also have widespread pain or depression (Bannuru et al., 2019).
- **Opioids:** The guideline strongly recommends against oral and transdermal opioids for OA because of the risk of dependence and little or no benefit (Bannuru et al., 2019). Opioid safety is taught in section 5.4.

NSAID risks are serious, and many people buy NSAIDs without a prescription. The Canadian celecoxib monograph, which describes risks shared across the class, warns of heart attack and stroke, stomach ulcers and bleeding that can occur without warning, fluid and sodium retention that can raise blood pressure and worsen heart failure, and kidney injury (Nora Pharma Inc., 2026). Kidney risk is highest in people who are older or dehydrated, who have kidney disease, heart failure or liver disease, or who take diuretics, angiotensin-converting enzyme (ACE) inhibitors or angiotensin receptor blockers (ARBs). Before giving an oral NSAID, the nurse reviews kidney function, blood pressure, fluid status, signs of bleeding and the full medication list, and reports concerns to the prescriber. Kidney disease is covered in section 27.3.

A **corticosteroid injection** into the knee is conditionally recommended in the OARSI guideline, but not for hip OA (Bannuru et al., 2019). The nurse teaches the person to report a joint that becomes hotter, more swollen or more painful in the days after an injection, because infection must be ruled out (section 34.1). Joint replacement is considered when pain and disability are significant and other treatments have not worked (Arthritis Society Canada, n.d.-b); surgery and recovery are taught in section 33.5.

OA affects more than the joint. Among working-age adults with OA in Canada, 42% are not in the labour force or in school, compared with 19% of the general population (Arthritis Society Canada, n.d.-a). The nurse asks about sleep, mood, work and caregiving, screens for low mood, and connects the person with physiotherapy, occupational therapy and community programs

(section 34.7). Cold packs may relieve swelling and brief flares of pain, and heat may relieve stiffness, but heat is not used on an inflamed joint. Pacing activities and relaxation techniques help many people cope (Arthritis Society Canada, n.d.-b).

Using the CJMM (section 1.4), the nurse watches for cues that the plan is causing harm or that something new is happening. Black stools, a rising creatinine or new swelling in the legs in a person taking an oral NSAID, or a single joint that is suddenly hot and swollen, are cues to hold the next NSAID dose as appropriate, report at once using SBAR (section 6.2) and evaluate the response.

PATIENT EDUCATION

Moving With Osteoarthritis

- Keep moving. Activity protects your joints; long periods of rest make stiffness and weakness worse.
- Start slowly and build up. Aim, over time, for 150 minutes of moderate activity a week, such as walking, cycling, swimming, water exercise, tai chi or yoga.
- Strengthen the muscles around the sore joint with the exercises your physiotherapist gives you.
- If you carry extra weight, losing about 10% of your body weight can ease knee pain.
- On a bad day, keep doing gentle range-of-motion exercises rather than stopping completely.
- Use cold packs for swelling. Use heat for stiffness, but not on a joint that is hot and swollen.
- Pace your day: break big jobs into smaller ones and rest between them.
- Use a cane, brace or other aid if your therapist recommends it, and ask how to use it correctly.
- Read medicine labels. Many cold, flu and pain products contain an NSAID or acetaminophen. Ask a pharmacist before combining products, and do not use a skin gel and an anti-inflammatory pill at the same time unless your prescriber says to.
- Get help quickly if a joint suddenly becomes hot, red or very swollen, or if you have black stools or vomit blood.

(Arthritis Society Canada, n.d.-b; Haleon Canada ULC, 2026)

LIFESPAN CONSIDERATIONS

Arthritis in Older Adults

- **NSAIDs:** Older adults are more sensitive to NSAID side effects and tolerate stomach ulcers and bleeding less well; most reports of fatal stomach and bowel events with celecoxib involved older adults (Nora Pharma Inc., 2026). The OARSI guideline does not recommend oral NSAIDs for people with frailty or cardiovascular disease (Bannuru et al., 2019). Older age also raises the risk of kidney injury from NSAIDs (Nora Pharma Inc., 2026).
- **Falls:** Pain, stiffness, weak muscles and poor balance raise the risk of falling. The nurse checks footwear, walking aids, lighting and the route to the bathroom (section 8.4). Osteoporosis, which makes a fracture after a fall more likely, is covered in section 33.3.
- **Many medicines:** An older adult may take several prescription and over-the-counter products for pain. The nurse reviews them all for duplicates and interactions (section 8.5).
- **Living alone:** Stiff hands and painful knees can make cooking, bathing and opening pill bottles difficult. Occupational therapy, easy-open containers and home supports help people stay independent.
- **Mood:** Chronic pain and lost independence can lead to depression, which may look like withdrawal, poor appetite or poor sleep rather than sadness (section 8.3).

34.3 Rheumatoid Arthritis

What Happens in Rheumatoid Arthritis

Rheumatoid arthritis (RA) is a chronic autoimmune disease in which the immune system attacks the lining of the joints, causing inflammation, swelling, pain and stiffness (Arthritis Society Canada, n.d.-c; PHAC, 2020c). The inflamed synovium thickens and, if not controlled, wears away cartilage and bone, leaving joints damaged and deformed. There is no cure, but treatment can control the inflammation (Arthritis Society Canada, n.d.-c; Figure 34.4).

RA often starts in a few joints and spreads to others over weeks to months, although it sometimes progresses quickly. It typically affects the same joints on both sides of the body, especially the small joints of the hands, wrists and feet, but also the elbows,

shoulders, knees and ankles. Morning stiffness lasting 30 minutes or more, warmth over the joints, reduced movement and firm lumps under the skin (rheumatoid nodules), most often near the elbows, hands or feet, are typical. Early symptoms can be vague: feeling unwell or tired, aching muscles, a low-grade fever, weight loss and poor appetite (Arthritis Society Canada, n.d.-c). A **flare** is a period when symptoms suddenly return or worsen; flares usually settle within a few weeks (Arthritis Society Canada, n.d.-c).

Figure 34.4 Chronic joint changes of rheumatoid arthritis on both hands, including swelling and subluxation at the metacarpophalangeal joints and ulnar deviation of the fingers.

RA is a whole-body disease. Inflammation can also affect the eyes, lungs, heart, skin and nerves (Arthritis Society Canada, n.d.-c). People with diagnosed RA in Canada have a higher death rate than people without it (PHAC, 2020c). The nurse therefore pays attention to new shortness of breath, cough, chest pain or eye symptoms, and supports preventive care and screening tailored to the person's risk factors (Nikolic et al., 2026).

In 2016–2017, about 374,000 Canadians aged 16 and older had diagnosed RA, and about 23,000 were newly diagnosed. Prevalence was 1.7% among females and 0.8% among males, and rose with age (PHAC, 2020c). Known risk factors include family history and smoking (PHAC, 2020c). Smoking is the strongest known environmental risk factor, and gum disease is more common in people with RA (Arthritis Society Canada, n.d.-c). RA most often begins between ages 40 and 60 (Arthritis Society Canada, n.d.-c). In Alberta, RA affects about three times as many First Nations residents as non–First Nations residents (Barnabe et al., 2017; see the Canadian Context box in section 34.1).

Diagnosis and Treat-to-Target

Time matters in RA. The Canadian Rheumatology Association (CRA) states that all people with RA should be able to see a rheumatologist early, with fair (equitable) access to that care (Nikolic et al., 2026). Swelling of the joint lining that persists for 6 weeks or more on examination is the most reliable reason for an urgent referral to a rheumatologist, even before formal criteria are met (Jung & Barra, 2015). Arthritis Society Canada (n.d.-c) advises people to see a doctor if joint symptoms last more than 6 weeks; the family physician or nurse practitioner (NP) usually makes the referral.

No single test confirms RA. Diagnosis combines the history, joint examination, blood tests and sometimes X-rays or ultrasound (Arthritis Society Canada, n.d.-c). X-rays of the hands and feet may be normal early in the disease, while bone erosions typical of RA support the diagnosis (Jung & Barra, 2015). Blood tests are summarized in Table 34.2 and the Going Deeper box in section 34.1.

Treat-to-target means setting a clear goal for disease control, measuring disease activity at regular visits and changing treatment until the goal is reached. The CRA states that treatment should aim for remission or, when that is not possible, minimal disease activity, and should be tailored to the person through shared decision-making (Nikolic et al., 2026). The 2025 EULAR update recommends starting with methotrexate, ideally with short-term glucocorticoids (corticosteroids), and adding a biologic medicine if the response is not good enough after 3 to 6 months (Smolen et al., 2026). The CRA suggests short-term corticosteroids while disease-modifying drugs start to work, and recommends against routine long-term (more than 6 months) low-dose corticosteroids (Nikolic et al., 2026). When a person has been in remission or low disease activity for at least 6 months, gradually reducing medicines may be considered, but only through shared decisions and only when the person can reach rheumatology care quickly and restart treatment if the disease flares (Nikolic et al., 2026).

Nursing Care and Medicines

A **disease-modifying antirheumatic drug (DMARD)** slows or stops the immune process that damages joints, rather than only easing symptoms. NSAIDs relieve pain and swelling but do not change the course of RA (Arthritis Society Canada, n.d.-c).

Methotrexate is central to RA care. Arthritis Society Canada (n.d.-c) names it as the most common DMARD, and the 2025 EULAR update recommends it as the first treatment, ideally with short-term glucocorticoids (Smolen et al., 2026). The CRA living guideline update does not name a first drug in its published letter. For RA, methotrexate is taken **once a week**, on the same day each week, not daily. The Canadian monograph warns that taking the weekly dose every day by mistake has caused fatal toxicity (JAMP Pharma Corporation, 2024). Institute for Safe Medication Practices Canada (ISMP Canada) has received reports of serious harm and death from daily use, often when orders were written, transcribed or dispensed as daily or when patients misunderstood the schedule. Because most medicines are taken daily, a weekly schedule is easy to get wrong (Blinova et al., 2008). Safety strategies include:

- naming a specific day of the week on every order, label and medication administration record (avoiding Monday, which can be misread as "morning");
- taking extra care with the medication history whenever a person taking methotrexate is admitted, and checking frequency and indication before any dose;
- teaching every person who starts or changes methotrexate, with written information about the weekly schedule and a calendar to record doses and blood tests (Blinova et al., 2008).

Methotrexate is usually prescribed together with **folic acid**, which helps limit side effects (Arthritis Society Canada, n.d.-c). The monograph notes that folic or folinic acid may lessen some toxicities, such as stomach and bowel upset, mouth sores and hair loss (JAMP Pharma Corporation, 2024). The person takes folic acid exactly as ordered, on the days the prescriber specifies.

Monitoring is part of every methotrexate plan. The Canadian monograph calls for baseline blood, liver and kidney tests and a chest X-ray, then blood counts at least monthly and liver and kidney tests every 1 to 2 months in people with RA (JAMP Pharma Corporation, 2024); the rheumatologist sets each person's schedule. The monograph lists alcohol use with methotrexate as contraindicated, and the patient information tells people not to drink alcohol (JAMP Pharma Corporation, 2024).

Methotrexate lowers the body's defences. Mouth sores can be an early sign of toxicity. The person should report fever, sore throat or other signs of infection, diarrhea or vomiting, unusual bruising or bleeding, and a dry cough or shortness of breath, which can signal lung inflammation (JAMP Pharma Corporation, 2024). Whether to hold a dose during an infection or before surgery is decided by the prescriber; the nurse does not stop or restart methotrexate on their own. Live vaccines are generally not recommended during treatment (JAMP Pharma Corporation, 2024); adult immunization is taught in section 21.6.

Pregnancy needs planning. Methotrexate can cause fetal death and birth defects, and pregnancy should be avoided if either partner is taking it. Published advice on how long to wait after stopping before trying to conceive ranges from 3 months to one year (JAMP Pharma Corporation, 2024). The nurse encourages anyone who may want a pregnancy to talk with the rheumatologist well before stopping contraception.

Other conventional DMARDs, such as hydroxychloroquine, sulfasalazine and leflunomide, may be added, and biologic and targeted medicines are used when conventional DMARDs are not enough (Arthritis Society Canada, n.d.-c). These medicines, and the screening needed before starting them, are covered in section 34.6.

Nurses also teach ways to live well with RA. EULAR recommends that nurses offer education based on each person's needs, psychosocial support and help with self-management, within a team and through shared decisions (Bech et al., 2020). Therapy, education and medicines are all part of RA care (PHAC, 2020c). Key strategies include:

- **Joint protection:** keeping joints aligned, limiting high-stress tasks, pacing activities and using assistive devices such as jar openers (Arthritis Society Canada, n.d.-b).
- **Energy conservation:** planning the day, spreading tasks out and resting before becoming exhausted can help with fatigue.
- **Splints and therapy:** occupational therapists provide splints and adaptive equipment; physiotherapists build safe exercise programs (Arthritis Society Canada, n.d.-b; PHAC, 2020c).

- **Mental health:** People with arthritis are up to 2 to 3 times as likely as people without it to have a mood disorder such as depression (Arthritis Society Canada, n.d.-a). The nurse asks about mood, sleep and concentration and offers support.
- **Work:** Flexible hours, workplace changes and early discussion with an employer help people keep working (section 34.7).

Hospital admission is a risky time for people with RA. Applying the CJMM, the nurse recognizes cues such as a weekly medicine ordered daily, a fever in a person taking methotrexate, or one joint far more swollen than the others; analyzes them against the person's usual pattern; and acts and escalates with SBAR (section 6.2).

Table 34.2 Tests used in arthritis and what they show (Aringer et al., 2019; Arthritis Society Canada, n.d.-c; JAMP Pharma Corporation, 2024; Jung & Barra, 2015; PHAC, 2020a; Weston & Coakley, 2006)

Test	What it measures	Typical finding	Nursing point
C-reactive protein (CRP), mg/L	A protein the liver makes during inflammation	Often raised in active inflammatory arthritis; also raised by infection and injury	Not specific; compare with earlier results and the person's symptoms
Erythrocyte sedimentation rate (ESR), mm/h	How quickly red blood cells settle; rises with inflammation	Often raised in active inflammatory arthritis	Not specific; affected by many other conditions
Rheumatoid factor (RF)	An antibody often present in RA	May be positive in RA; also positive in some other conditions	A negative result does not rule out RA
Anti-CCP antibodies	Antibodies to cyclic citrullinated peptides	More specific for RA than RF	A negative result does not rule out RA
Antinuclear antibodies (ANA)	Antibodies against parts of the cell nucleus	A positive ANA is required to classify lupus under the 2019 EULAR/ACR criteria	See section 34.5
Serum urate, µmol/L	Uric acid in the blood	Used to diagnose and monitor gout	See section 34.4
Complete blood count, liver tests, creatinine	Blood cells, liver injury and kidney function	Used at baseline and regularly during methotrexate treatment	Report low white cells or platelets, rising liver enzymes or rising creatinine
Joint fluid analysis	Infection and crystals in fluid drawn from a joint	Uric acid crystals in gout; calcium pyrophosphate crystals in pseudogout	When infection is possible, fluid is drawn before antibiotics start
Hand and foot X-rays	Bone and joint changes	May be normal early in RA; erosions support the diagnosis	Prepare the person; explain why images are repeated

PRACTICE STORY

Once a Week

Names and details are fictional; this is a composite story.

Nurse: Kwabena Asante, RN. Years in practice: 7. Setting: medical unit, Ontario.

Mr. Henri Gagnon was 81 and came up from emergency with worsening heart failure. His daughter, Sylvie, had brought a bag of his medicines and a blister pack from his pharmacy. During medication reconciliation, I compared the admission orders with what he actually took at home.

One line stopped me: methotrexate, by mouth, once daily. Mr. Gagnon had rheumatoid arthritis, and in the blister pack his methotrexate sat in one slot only, on Saturday. Sylvie confirmed it: "Dad takes those little pills on Saturdays. The folic acid is separate." The daily order had come from a list that was transcribed in emergency.

His next dose on the electronic record was due that evening. I did not give it. I flagged the order, documented why, and called the hospitalist and our unit pharmacist. Within the hour, the order was corrected to once weekly on Saturday, with a note from the prescriber about whether to give this week's dose while he was acutely ill. The pharmacist and I also checked that no dose had been given in emergency. None had.

I filed a safety report. It was not about blame; a daily order for a weekly medicine had passed through two steps, and the unit needed to know.

> Before discharge, I sat with Mr. Gagnon and Sylvie. We wrote "METHOTREXATE: SATURDAY ONLY" on a calendar and talked about what to watch for: mouth sores, fever, a sore throat, a new dry cough, bruising. Sylvie said she had never known why the pills were in only one slot. "Now I'll check every time he goes anywhere," she said.
>
> I think about how easy it would have been to click "given."
>
> Reflect: Which parts of Kwabena's actions could an RPN on the same unit carry out within their own scope, and at what point should the RPN involve the RN or the prescriber? What system changes could stop a daily methotrexate order from reaching the medication record again?

34.4 Gout

The Public Health Agency of Canada (PHAC) describes gout as the most common form of inflammatory arthritis (PHAC, 2020a). Taken over the long term, the right medicines can prevent flares and joint damage. Nurses meet people with gout in clinics and emergency departments, and on medical and surgical units, where a sudden hot joint can appear during a stay for something else.

What Happens in Gout

Uric acid is a waste product the body makes when it breaks down purines, substances found in body cells and in many foods. The kidneys remove most of it. When the level of urate in the blood stays high for a long time (hyperuricemia), crystals of monosodium urate can form and settle in and around joints and in other tissues. **Gout** is the disease caused by this crystal deposit (Neogi et al., 2015). Many people with a high urate level never develop gout, and the 2020 ACR gout guideline (a US guideline) advises against treating a high level that causes no symptoms (FitzGerald et al., 2020).

A **gout flare** happens when the immune system reacts to the crystals. Over a few hours, a joint becomes swollen, warm and very painful. The joint at the base of the big toe (the first metatarsophalangeal joint), the ankle and the midfoot are common sites (Neogi et al., 2015). Redness is easy to see on lighter skin but may be hard to see on darker skin, so the nurse feels for warmth, looks for swelling, compares the joint with the other side and asks the person how it feels (section 34.1; Chapter 35). Over time, flares may come more often and last longer, and repeated flares can damage the joint permanently (PHAC, 2020a).

Over years, crystals can build up as a **tophus** (plural tophi), a firm, chalk-like lump under the skin, often on the ear, the elbow or the pads of the fingers (Neogi et al., 2015). Urate can also form kidney stones (Chapter 28) (Figure 34.5).

Data from the Canadian Chronic Disease Surveillance System show that in 2016–2017, about 681,000 people in Canada aged 20 and older (2.4%) had diagnosed gout or another crystal arthritis, and about 54,000 were newly diagnosed that year. Prevalence was 3.7% among males and 1.1% among females and rose with age, and age-standardized prevalence increased between 2007–2008 and 2016–2017 (PHAC, 2020a). PHAC names obesity, diet, alcohol and certain medicines as contributing factors. The US guideline also addresses chronic kidney disease, thiazide diuretics such as hydrochlorothiazide, and drinks sweetened with high-fructose corn syrup (FitzGerald et al., 2020). Because kidney disease and medicines also play a part, the nurse avoids language that treats gout as the result of poor choices.

Finding urate crystals in joint fluid or in a tophus confirms gout (Neogi et al., 2015; see the Going Deeper box in section 34.1). A hot, swollen joint can also be septic arthritis, which is an emergency, so a new hot joint in a person with fever or who looks unwell is reported promptly (Chapter 4).

Care During a Flare and Between Flares

During a flare, the goal is to relieve pain and inflammation quickly. The nurse helps the person find a comfortable position for the joint and applies ice; the US guideline supports topical ice as an add-on to medicine (FitzGerald et al., 2020). The guideline names three first-line choices: colchicine, an NSAID, or a corticosteroid given by mouth, into the joint or into a muscle. When colchicine is used, it prefers low-dose over high-dose colchicine, and it suggests a corticosteroid for people who cannot take anything by mouth (FitzGerald et al., 2020). Colchicine works best when it is started early in a flare. Its Canadian product monograph warns that stomach and bowel symptoms, such as nausea, vomiting and diarrhea, are the first signs of toxicity, that drugs such as clarithromycin can raise colchicine to dangerous levels, and that older adults and people with kidney or liver disease need extra care (Pharmascience, 2016). NSAID risks are covered in section 34.2, and corticosteroid effects in section 34.6.

Between flares, the aim is to dissolve the crystals by lowering the urate level. **Urate-lowering therapy** (ULT) is a long-term medicine that lowers the amount of urate in the body. The US guideline strongly recommends ULT for people with one or more tophi, joint damage on imaging or two or more flares a year (FitzGerald et al., 2020). Allopurinol is the preferred first medicine, including for people with chronic kidney disease of stage 3 or higher (Chapter 27). Febuxostat is an alternative, but the guideline suggests switching to another medicine for people with cardiovascular disease. ULT starts at a low dose and is raised step by step, guided by repeated blood tests, until the serum urate stays below 360 µmol/L (6 mg/dL in the US guideline; FitzGerald et al., 2020; conversion from Neogi et al., 2015). The ACR guideline (US) strongly recommends this treat-to-target approach and keeping the urate below the target once it is reached, and it suggests continuing ULT indefinitely. It also supports dose adjustment by nurses and other non-physician providers who follow a protocol and provide education and shared decision-making (FitzGerald et al., 2020).

Figure 34.5 Tophaceous gout at the first metatarsophalangeal joint with hallux valgus in an older adult; cropped to the foot for patient privacy. (credit: modification of "Tophaceous gout of Lt MTP joint, elder female patient, Thailand" by Chainwit./Wikimedia Commons, CC BY 4.0)

Flares can occur in the first months of ULT. For this reason, the guideline strongly recommends a preventive anti-inflammatory medicine (colchicine, an NSAID or prednisone) for 3 to 6 months after ULT begins, and it suggests that ULT can be started during a flare (FitzGerald et al., 2020). The nurse explains this in advance, so that the person does not decide that the new medicine has failed and stop it.

The US guideline suggests testing for HLA-B*5801, a gene variant linked to severe allergic reactions to allopurinol, before allopurinol is started in patients of Southeast Asian descent (for example, Han Chinese, Korean or Thai) and in African American patients, and not routinely in others (FitzGerald et al., 2020). Every person starting allopurinol is taught to report any new rash at once (Chapter 21).

The guideline also suggests limiting alcohol, purine-rich foods and high-fructose corn syrup, and losing weight for people who are overweight; it does not support vitamin C supplements (FitzGerald et al., 2020). The nurse presents these steps as support for the medicines, not as a test of willpower. The prescriber may change hydrochlorothiazide to another blood pressure medicine, and the guideline advises against stopping low-dose acetylsalicylic acid (ASA) that a person takes for a heart or stroke condition (FitzGerald et al., 2020).

In hospital, a person with gout can flare during a stay for another problem, and certain medicines, such as thiazide diuretics, can contribute (PHAC, 2020a; FitzGerald et al., 2020). The nurse continues ULT unless the prescriber holds it and reports a new hot joint promptly, especially with fever, because septic arthritis must be ruled out (section 34.1; Chapter 4). Older adults face higher risks from colchicine and NSAIDs, so the nurse watches kidney function and new medicines closely (Chapter 8).

PATIENT EDUCATION

Preventing Gout Flares

- **Take your urate-lowering medicine every day,** even when your joints feel fine. It works slowly and prevents flares only when it is taken long term.
- **Go for your blood tests.** Your dose is adjusted until your urate level reaches the target your prescriber has set.

- **Expect some flares at first.** Flares in the first months do not mean the medicine is failing. Take the preventive medicine for as long as it is prescribed.
- **Have a flare plan.** Know which medicine to start and start it early. Rest the joint, raise it and use ice.
- **If you take colchicine,** stop it and call your prescriber or pharmacist if you get diarrhea or vomiting. Tell every prescriber and pharmacist that you take it before you start a new medicine, such as an antibiotic. Store it out of reach of children, because an overdose can kill a child.
- **If you take allopurinol,** call your prescriber at once if you get a rash.
- **Limit alcohol, purine-rich foods and sweet drinks** made with high-fructose corn syrup. A dietitian can help you plan meals you enjoy.
- **Get care the same day** for a hot, swollen joint with fever or chills, or if you feel unwell.

34.5 Lupus and Other Connective Tissue Disorders

Connective tissue disorders are autoimmune diseases that can affect the skin, joints, blood vessels and internal organs. This section covers systemic lupus erythematosus in depth and four related conditions in brief (Table 34.3). Autoimmunity is reviewed in Chapter 21.

Systemic Lupus Erythematosus

Systemic lupus erythematosus (SLE, often called lupus) is a chronic autoimmune disease in which the immune system makes antibodies against parts of the body's own cells, causing inflammation in many organs. The 2019 European League Against Rheumatism/American College of Rheumatology (EULAR/ACR) classification criteria require a positive ANA test as the starting point and then score findings across clinical and immune domains. The criteria are designed to classify people for research, not to diagnose an individual (Aringer et al., 2019).

SLE affects women far more often than men. In an Alberta study of health records from 1994 to 2007, SLE prevalence was 27.3 per 10,000 females and 3.2 per 10,000 males. Among women older than 45, the combined prevalence of SLE or systemic sclerosis was twice as high for First Nations women as for non–First Nations women. The authors noted that this could reflect a true difference or systematic differences in health care delivery, and they called for adequate access to specialists and treatment (Barnabe et al., 2012). The study used provincial administrative data; the OCAP® principles described in section 34.1 apply to how such data are used (Chapter 2). In a Canadian cohort of 1,416 adults with SLE, kidney involvement was more common among Asian and Afro-Caribbean participants. Low income, not ethnicity, predicted organ damage over time. Indigenous participants had the lowest incomes, and the authors noted that lower rates of specialist contact have been documented for Indigenous people (Peschken et al., 2009). These findings point to structural causes, such as poverty and distance from care, rather than to race as biology (Chapter 2).

SLE varies widely from person to person. The clinical findings that the classification criteria score include the following (Aringer et al., 2019):

- fever;
- joint involvement;
- lupus skin rashes and mouth ulcers; (Figure 34.6)
- inflammation of the lining around the lungs or heart (serositis), or fluid around them;
- kidney inflammation (lupus nephritis);
- a low white blood cell count;
- delirium, psychosis or seizures.

People with SLE also often report fatigue, pain, low mood and problems with thinking, which may not improve with immunosuppressive medicines (Fanouriakis et al., 2024). Lupus is characteristically sensitive to sunlight, a feature called **photosensitivity** (Fanouriakis et al., 2024). Redness can be harder to see on darker skin, so the nurse compares any rash with the person's usual skin colour, asks what has changed and checks the scalp, ears and mouth (Chapter 35).

Lupus nephritis, inflammation of the kidneys caused by SLE, is one of its most serious forms. The team tracks protein in the urine, kidney function and blood pressure, which EULAR advises keeping below 130/80 mm Hg (Fanouriakis et al., 2024). New swelling, rising blood pressure and falling urine output are reported promptly (Chapter 27). Treatment combines immunosuppressive medicines and continues for at least 3 years after the kidneys respond (Fanouriakis et al., 2024).

In SLE, a flare (section 34.3) is a period of increased disease activity. Because of the disease's photosensitivity, EULAR advises people with lupus to avoid sun exposure in particular (Fanouriakis et al., 2024). Fever in a person with SLE may be a flare or an infection, and the two can look alike, especially in someone taking corticosteroids or other immunosuppressants. The nurse reports fever promptly so that the team can look for infection before more immunosuppression is given (Chapter 4).

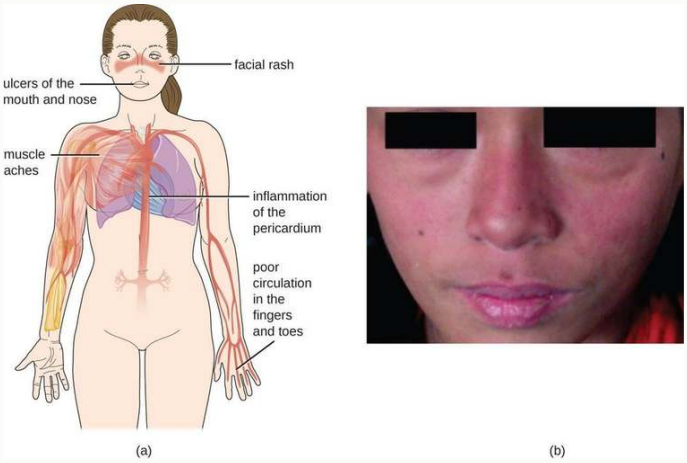

Figure 34.6 Systemic lupus erythematosus: (a) common organ and tissue involvement across the body; (b) a butterfly (malar) rash across the cheeks and nasal bridge, sparing the creases beside the nose. (credit: "OSC Microbio 19 02 Lupus" by CNX OpenStax/Wikimedia Commons, CC BY 4.0)

EULAR's treatment goal is remission or, when that is not possible, low disease activity. Disease activity is checked at every visit, and care is multidisciplinary, with education and shared decision-making (Fanouriakis et al., 2024). Medicines include the following:

- **Hydroxychloroquine** is recommended for everyone with SLE unless it is unsafe for them, and EULAR advises against stopping it in remission (Fanouriakis et al., 2024). Because it can damage the retina, a current Canadian monograph calls for an examination of both eyes before long-term treatment and at least once a year after that. It also warns of severe hypoglycemia, which can cause loss of consciousness, and that children are especially sensitive to this drug group, with deaths reported after accidental swallowing (Auro Pharma, 2026). EULAR advises closer eye follow-up for people at higher risk of retinal damage, such as those with kidney disease (Fanouriakis et al., 2024).
- **Corticosteroids** control active disease. EULAR advises reducing them to the lowest maintenance dose and stopping them when possible (Fanouriakis et al., 2024).
- **Methotrexate, other immunosuppressants and biologics** such as belimumab are added when hydroxychloroquine is not enough or corticosteroids cannot be reduced (Fanouriakis et al., 2024). The belimumab monograph warns of serious infections, hypersensitivity reactions, depression and suicidal thoughts (GlaxoSmithKline, 2025).
- **Long-term anticoagulation** is used for people whose SLE is complicated by blood clots from antiphospholipid antibodies (Fanouriakis et al., 2024; Chapter 19).

EULAR also calls for vaccines (including influenza, pneumococcal, shingles, human papillomavirus and COVID-19), bone health care, kidney protection, cardiovascular risk management and cancer screening, along with sun protection, not smoking, a healthy diet and regular exercise (Fanouriakis et al., 2024). Pregnancy planning is covered in separate EULAR recommendations. The nurse encourages people who could become pregnant to plan with their rheumatology team, because some medicines need to be reviewed before conception.

Other Connective Tissue Disorders and Vasculitis

Systemic sclerosis (SSc, also called scleroderma) is a rare autoimmune disease that damages small blood vessels and causes fibrosis, a thickening and scarring of the skin and internal organs. Among rheumatic diseases, it has the highest rates of illness and death (Del Galdo et al., 2025). **Raynaud phenomenon** is one of its blood vessel features: in cold or under stress, small arteries in the fingers or toes spasm, and the skin changes colour and may feel numb or painful until blood flow returns. Colour changes may be harder to see on darker skin, so the nurse asks about numbness, pain and colour change compared with the person's usual skin. EULAR recommends a calcium channel blocker as first-line treatment. SSc can also cause finger ulcers, lung scarring, high pressure in the lung arteries and reflux. **Scleroderma renal crisis** is a serious kidney complication. It is treated at once with an ACE inhibitor, and

EULAR recommends regular blood pressure checks for people with SSc who take corticosteroids so that it is found early (Del Galdo et al., 2025; Figure 34.7).

Figure 34.7 Well-demarcated digital pallor on exposure to cold in Raynaud phenomenon.

Sjögren disease (also called Sjögren syndrome) is a systemic autoimmune disease marked by dry eyes and a dry mouth, with fatigue and pain. It can affect other organs, and lymphoma develops in about 2% to 5% of people (Ramos-Casals et al., 2020). Care protects the teeth and eyes: sugar-free gum or lozenges, saliva substitutes, fluoride gel, regular dental care, artificial tears in the day and ointment at night (Ramos-Casals et al., 2020).

Vasculitis is inflammation of blood vessel walls. **Polymyalgia rheumatica** (PMR) affects adults aged 50 and older. It causes aching and stiffness in both shoulders and often the hips, morning stiffness that lasts more than 45 minutes and a raised CRP or ESR (section 34.1; Dasgupta et al., 2012). PMR is treated with corticosteroids rather than NSAIDs, for the shortest effective time, with a taper planned for each person, and an exercise program helps keep muscle strength and prevent falls (Dejaco et al., 2015). The 2025 EULAR recommendations allow methotrexate or an interleukin-6 (IL-6) blocker such as tocilizumab to be added for selected people (Mukhtyar et al., 2026).

Giant cell arteritis (GCA) is a vasculitis of large arteries, including arteries of the head, in adults older than 50. Typical presentations include headache, pain in the jaw when chewing (jaw claudication), visual symptoms and PMR; the scalp may also be very tender, as in a recent Canadian case report (Ghebrial et al., 2026). GCA is a rheumatologic emergency because it can cause permanent loss of vision and stroke (Ghebrial et al., 2026). The international 2025 EULAR recommendations state that anyone suspected of having GCA needs urgent specialist referral, that people with cranial symptoms (such as headache, jaw pain or visual changes) are at high risk of permanent vision loss and should be referred immediately, and that when suspicion is strong, corticosteroid treatment should start without delay while confirmatory tests are pending. Fast-track clinics have reduced permanent vision loss (Mukhtyar et al., 2026). A CRP test and, where available, an urgent ultrasound of the temporal arteries support the diagnosis, and a temporal artery biopsy remains the reference test (Ghebrial et al., 2026). An IL-6 blocker such as tocilizumab may be added for some people, especially those whose disease relapses or who are at high risk of corticosteroid side effects (Mukhtyar et al., 2026). Any nurse who hears these symptoms escalates the same day.

Table 34.3 Connective tissue disorders and vasculitis compared (Aringer et al., 2019; Dasgupta et al., 2012; Del Galdo et al., 2025; Fanouriakis et al., 2024; Ghebrial et al., 2026; Mukhtyar et al., 2026; Ramos-Casals et al., 2020; original wording)

Disorder	Main features	Danger signs to report	Nursing focus
Systemic lupus erythematosus	Fatigue, fever, joint pain, rashes, mouth ulcers, serositis, kidney and blood changes	Fever; chest pain with breathing; new swelling or less urine; rising blood pressure; confusion or seizure	Hydroxychloroquine every day and yearly eye checks; sun protection; urine, creatinine and blood pressure; infection watch
Systemic sclerosis	Thick, tight skin; Raynaud phenomenon; finger ulcers; reflux; lung and kidney involvement	A finger that stays pale or dark or has an ulcer; a rise in blood pressure or less urine; new shortness of breath	Warmth and skin care; blood pressure checks, especially with corticosteroids; reflux and swallowing care

Disorder	Main features	Danger signs to report	Nursing focus
Sjögren disease	Dry eyes, dry mouth, fatigue, pain	Worsening eye or mouth symptoms; new symptoms in other organs	Mouth and dental care; artificial tears; referral to dentist and eye specialist as needed
Polymyalgia rheumatica	Age 50 or older; aching and stiffness of both shoulders and hips; morning stiffness; raised CRP or ESR	New headache, scalp tenderness, jaw pain on chewing or any vision change (possible GCA)	Corticosteroid teaching; exercise and fall prevention; teaching the warning signs of GCA
Giant cell arteritis	New headache, scalp tenderness, jaw pain on chewing, visual symptoms, PMR symptoms	Any vision change, even brief; symptoms of stroke	Same-day escalation; corticosteroids without delay as ordered; safety if vision is affected

CLINICAL JUDGMENT

A Headache and Jaw Pain

Names and details are fictional; this is a composite story.

Hélène Gagnon, 76, has had polymyalgia rheumatica for 8 months and takes prednisone. On Tuesday morning she calls the rheumatology clinic's nurse line. For 4 days she has had a new headache on the right side, her scalp hurts when she brushes her hair, and her jaw aches when she chews, so she stops partway through meals. This morning the vision in her right eye "went blurry for a few minutes." Her shoulder stiffness is no worse.

- **Recognize cues:** A new headache, scalp tenderness, jaw pain with chewing and a brief change in vision in a 76-year-old woman with PMR.
- **Analyze cues:** Together, these findings fit giant cell arteritis, which can occur in people with PMR. Brief blurred vision is a warning that permanent vision loss may follow.
- **Prioritize hypotheses:** GCA threatening her sight comes ahead of a tension headache, a dental problem or a side effect of prednisone.
- **Generate solutions:** She needs specialist assessment and treatment today, through the clinic's urgent pathway or, if that cannot happen within hours, the emergency department. She should not drive.
- **Take action:** The nurse tells Mrs. Gagnon not to wait and stays on the line while they confirm that her son can bring her in. The nurse reaches the rheumatologist at once and gives an SBAR report (Chapter 6). The rheumatologist sees her that afternoon, orders blood tests and starts high-dose corticosteroids. The nurse documents the call.
- **Evaluate outcomes:** The next day, Mrs. Gagnon's headache is easing and her vision has not changed again. Her temporal artery ultrasound is booked. The nurse teaches her to go to the emergency department at once for any new vision change and not to stop or reduce prednisone on her own.

34.6 Medicines for Inflammatory Arthritis

A DMARD (section 34.3) slows the disease process and protects joints and organs, rather than only easing symptoms. DMARDs fall into three groups: conventional synthetic DMARDs, biologics and targeted synthetic DMARDs (JAK inhibitors). Corticosteroids are also used, mainly for short periods. Gout medicines are described in section 34.4. Table 34.4 summarizes the main medicines in this chapter.

Conventional DMARDs

Methotrexate is the anchor drug for rheumatoid arthritis and is taken once a week (section 34.3). Hydroxychloroquine, sulfasalazine and leflunomide are other conventional DMARDs; hydroxychloroquine's eye and blood sugar warnings are described in section 34.5.

Biologics and Biosimilars

A **biologic** is a medicine made in living cells, usually a protein such as an antibody, that blocks one part of the immune response. Biologics are given by injection under the skin or by intravenous infusion. In arthritis and connective tissue disease, they include the

tumour necrosis factor (TNF) inhibitors adalimumab, etanercept, infliximab and golimumab; IL-6 blockers such as tocilizumab; rituximab, which removes B cells; and belimumab for SLE (section 34.5).

A **biosimilar** is a highly similar and generally less expensive version of an original (originator) biologic. Health Canada approves a biosimilar only after finding that it does not differ in any meaningful way from the originator in safety or effectiveness, and studies show little or no difference when people switch (Government of Ontario, 2025). Under Ontario's policy, people covered by the Ontario Drug Benefit program who took originator adalimumab, etanercept, infliximab or rituximab had to switch to a biosimilar during 2023 to keep their coverage, with some exemptions, and further biologics have since been added to the policy (Government of Ontario, 2025). Policies differ by province and territory. The nurse reassures the person, teaches the new injection device and updates the medication list with the new brand name.

JAK Inhibitors

A **JAK inhibitor** is a tablet that blocks Janus kinase (JAK) enzymes inside immune cells, interrupting signals from many inflammatory messengers. Tofacitinib and upadacitinib are examples. In November 2022, Health Canada announced that the Canadian labelling of all JAK inhibitors was being updated to include "risks of serious heart-related problems, fatal blood clots and cancer." Health Canada advises particular caution in older adults; in current or past smokers; in people who have other risk factors for heart disease or cancer, or who have cancer; and in people with a higher risk of blood clots. It tells people taking a JAK inhibitor to stop it and contact their health care professional immediately if they develop symptoms of a heart problem, such as new or worsening chest pain, shortness of breath, irregular heartbeats or swelling of the legs. People with symptoms of a blood clot, such as swelling, pain or tenderness in an arm or leg, or sudden unexplained chest pain or shortness of breath, should stop the medicine and seek immediate medical help (Health Canada, 2022).

Screening Before Starting

Before a biologic or JAK inhibitor begins, the team checks for infections that the medicine could reactivate:

- **Tuberculosis (TB):** The Canadian Tuberculosis Standards list people starting TNF inhibitors, other biologics and DMARDs, and higher-dose corticosteroids among those to test for TB infection, using a tuberculin skin test (TST) or an interferon-gamma release assay (IGRA) (Campbell et al., 2022). Anyone with a positive result is referred for a medical evaluation to exclude TB disease (Campbell et al., 2022), and TB infection is treated before therapy starts (AbbVie, 2022).
- **Hepatitis B:** People at risk are checked for past hepatitis B infection (AbbVie, 2022).
- **Vaccines:** The Canadian Immunization Guide advises immunizing before planned immunosuppression when possible, so vaccines are given before starting, as the guide and the prescriber direct. Influenza, pneumococcal and recombinant shingles vaccines are recommended for immunocompromised adults (PHAC, 2026). Live vaccines are avoided during treatment (AbbVie, 2022; GlaxoSmithKline, 2025).

Infection Risk and Injections at Home

These medicines lower defences against infection. The adalimumab monograph says that treatment should not start during an active infection and should stop if a serious infection develops (AbbVie, 2022). The nurse teaches the person to call the prescriber before the next dose if they have a fever, chills, a cough, burning on urination or a red, hot, painful area of skin, and to hold a dose only as the prescriber directs. Many people learn to inject at home. The nurse teaches the technique and site rotation, how to store the medicine as the label directs and how to use a puncture-resistant sharps container. Belimumab's first self-injection is supervised by a health care professional (GlaxoSmithKline, 2025).

Corticosteroids

Corticosteroids act quickly and are used for flares of gout, RA and SLE and as the main treatment for PMR and GCA. A joint guideline lists weight gain, high blood glucose, high blood pressure and bone loss among the effects to discuss when they start (Beuschlein et al., 2024). Long-term use also raises infection risk (see Screening Before Starting) and contributes to osteoporosis (Chapter 33). Taken for more than a few weeks, corticosteroids, including those injected into joints, can suppress the body's own cortisol production. A person on long-term therapy therefore never stops suddenly. The dose is tapered as ordered, and extra doses

may be needed during illness or surgery to prevent adrenal crisis (Beuschlein et al., 2024; Chapter 23). The general rule is the lowest dose for the shortest time (Dejaco et al., 2015; Fanouriakis et al., 2024).

In Hospital

At medication reconciliation, the nurse asks about injections and infusions taken weekly, every few weeks or monthly, and the date of the last dose, and does not rely only on a list of daily medicines. Methotrexate's weekly schedule needs the same care (section 34.3). DMARDs, biologics and JAK inhibitors are held or continued only as the prescriber directs, including around surgery (Chapter 7). Corticosteroids are not stopped, and the prescriber orders intravenous or intramuscular doses when the person cannot take them by mouth, is vomiting or is having surgery (Beuschlein et al., 2024).

Cost, Coverage and Access

Coverage shapes who can get these medicines. People may rely on provincial or territorial drug plans, private insurance or both. For eligible First Nations and Inuit, the Non-Insured Health Benefits (NIHB) program covers drugs on its list: open benefits, limited-use benefits that meet set criteria and, in special circumstances, exception drugs. NIHB covers benefits that are not available under other federal, provincial, territorial or private plans, and when the pharmacy bills NIHB directly, the person pays no deductible or co-payment (Indigenous Services Canada, n.d.). The nurse helps people with coverage forms and links them with the pharmacist and the prescriber's office, so that cost does not stop treatment.

Table 34.4 Medicines for arthritis and connective tissue disorders (Canadian product monographs; Health Canada, 2022; Government of Ontario, 2025; FitzGerald et al., 2020; Fanouriakis et al., 2024; original wording)

Drug or class	Canadian examples	Used for	Nursing points
Colchicine	colchicine	Gout flares; prevention of flares when urate-lowering therapy starts	Diarrhea or vomiting are early signs of toxicity; check for interacting drugs such as clarithromycin; extra care in older adults and kidney or liver disease; keep away from children
Urate-lowering therapy	allopurinol, febuxostat	Long-term gout control to a serum urate target	Taken every day for life; dose raised with blood tests; report any rash at once (allopurinol); expect early flares
Antimalarial DMARD	hydroxychloroquine	SLE (nearly everyone); RA	Eye examination before long-term use and at least yearly; can cause severe hypoglycemia; keep away from children
Conventional DMARDs	methotrexate, sulfasalazine, leflunomide	RA and other inflammatory arthritis; methotrexate also in SLE and PMR	Methotrexate once a week only; blood tests as ordered (section 34.3)
TNF inhibitors (biologics)	adalimumab, etanercept, infliximab, golimumab, and their biosimilars	RA and other inflammatory arthritis	TB and hepatitis B screening first; no live vaccines; report fever or infection before the next dose
Other biologics	rituximab, belimumab; tocilizumab (an IL-6 blocker)	RA (rituximab, tocilizumab); GCA (tocilizumab); SLE and lupus nephritis (belimumab)	Infusion or injection reactions; infection watch; belimumab: watch mood and report depression or suicidal thoughts
JAK inhibitors	tofacitinib, upadacitinib	RA and other inflammatory arthritis	Health Canada warnings: heart problems, blood clots, cancer; stop and seek care for chest pain, breathlessness or a swollen, painful limb
Corticosteroids	prednisone; corticosteroid joint injections	Flares; PMR; GCA; SLE	Lowest dose for the shortest time; never stop suddenly after long-term use; check blood glucose and blood pressure; bone protection

GOING DEEPER

Biologics, JAK Inhibitors and Screening Before Starting

Required for RN students; optional for PN students.

Biologics are large proteins that act outside cells. TNF inhibitors bind tumour necrosis factor, a messenger that drives joint inflammation; IL-6 blockers such as tocilizumab block the receptor for interleukin-6; rituximab binds a marker on B cells and removes them; belimumab blocks a factor that helps B cells survive. JAK inhibitors are small molecules that act inside the cell, where JAK enzymes relay signals from many cytokine receptors, so one tablet dampens several pathways at once.

Because both groups weaken defences against intracellular infections, screening is part of the plan. The Canadian Tuberculosis Standards place people receiving immunosuppressing drugs, such as TNF inhibitors or corticosteroids, in a high-risk group for progression from TB infection to TB disease; low-dose corticosteroids do not appear to raise the risk significantly. A TST induration of 5 mm or more counts as positive in people about to start biologics or other immunosuppressive therapy. Both the TST and the IGRA are less sensitive in people whose immune systems are already suppressed, so a negative result does not fully exclude infection. A positive result leads to a medical evaluation, and preventive treatment starts once TB disease has been excluded (Campbell et al., 2022).

For JAK inhibitors, the RN checks the person's history for smoking, heart disease, clots and cancer before the first dose and reports these to the prescriber, since Health Canada advises extra caution in these groups (Health Canada, 2022).

34.7 Living Well With Chronic Arthritis

Arthritis Society Canada reports that arthritis is one of the main causes of disability and work limitation in this country. Drawing on Canadian Community Health Survey data, it reports that pain limits the activities of more than 40% of people with arthritis, that roughly 4 out of 5 also live with another chronic health condition, and that working-age adults with arthritis report not taking part in the workforce at twice the rate of their peers. Depending on the age group, people with arthritis are as much as two to three times more likely than others to have depression or another mood disorder (Arthritis Society Canada, n.d.-a). Living well with arthritis therefore means caring for the whole person, not only the joints.

Pain, Fatigue, Sleep and Mood

Chronic pain and fatigue are often the problems people with arthritis most want help with. The nurse assesses both at each contact, using the approaches in Chapter 5, and asks how they affect sleep, work and daily life. Poor sleep can worsen pain and fatigue, so the nurse asks about sleep and teaches regular routines. Physical activity helps across these conditions: exercise is a first step in osteoarthritis (section 34.2), it is part of EULAR's advice for lupus (Fanouriakis et al., 2024), and it helps people with PMR keep muscle strength and avoid falls (Dejaco et al., 2015). Activity is paced: the person plans rest breaks, spreads tasks across the day and increases activity gradually.

Depression and anxiety are common and often missed. EULAR recommends that nurses address psychosocial issues to reduce symptoms of anxiety and depression (Bech et al., 2020). The nurse asks about mood using a screening tool the setting uses, listens for hopelessness, and refers the person for support. Some medicines, such as belimumab, carry warnings about depression and suicidal thoughts (GlaxoSmithKline, 2025). A person who describes thoughts of suicide is not left alone, and the nurse escalates at once.

Work, Income and Self-Management

Arthritis often begins in working years. People may need workplace accommodations, such as adjusted hours, modified tasks or equipment, and they may need help applying for benefits when they cannot work. The nurse asks about work early and links the person with an occupational therapist or a social worker when needed.

Self-management means the day-to-day skills a person uses to live with a chronic condition, including taking medicines, pacing activity, solving problems and knowing when to seek help. EULAR recommends that nurses support self-management skills to increase self-efficacy, a person's confidence that they can manage their condition (Bech et al., 2020). The nurse sets goals with the person, not for them, and builds on what the person already does well.

A written flare plan is one practical tool. Made with the rheumatology team, it lists the early signs of a flare, which medicines to start or continue, comfort measures such as rest, heat or ice, and whom to call and when. Joint protection and energy conservation (section 34.3) help the person keep up valued activities during a flare. Some people track pain, fatigue and stiffness in a diary or an

app and bring it to visits, which helps the team adjust treatment. The nurse checks that the person can read and use written material, offers it in the person's preferred language, including French, and includes family members when the person wishes.

The Team and Nurse-Led Care

Care for inflammatory arthritis and connective tissue disease is multidisciplinary (Fanouriakis et al., 2024; Ramos-Casals et al., 2020). The rheumatologist leads diagnosis and treatment; the physiotherapist plans exercise; the occupational therapist teaches joint protection and suggests aids; the pharmacist reviews medicines and interactions. The person's primary care provider and community nurses complete the team.

EULAR's recommendations on the nurse's role describe nurse-delivered education matched to the person's needs, nurse consultations, timely access to a nurse by telephone or virtual care, nurse participation in disease management and comorbidity screening, and extended roles for nurses with specialized training, according to national regulations (Bech et al., 2020). The US gout guideline similarly supports nurse-led titration of ULT under a protocol (FitzGerald et al., 2020).

Distance, Access and Cultural Safety

People in rural, remote and northern communities may need to travel long distances for specialist visits, infusions and eye examinations. EULAR recommends timely access to a nurse, including by telehealth (Bech et al., 2020), and telephone and virtual follow-up can reduce some travel. In SLE, documented lower specialist contact among Indigenous people and the link between low income and organ damage suggest that income and access shape outcomes (Peschken et al., 2009). Culturally safe care (Chapter 2) means that the nurse asks what matters to the person, respects their knowledge of their own body, welcomes family and community supports, including traditional healing when the person wants it, and helps them navigate coverage such as NIHB (section 34.6). For older adults, the nurse also watches for falls, isolation and the medicine burden of several conditions at once (Chapter 8).

SCOPE IN PRACTICE

Arthritis Care and Who Does What

Every nurse, RN or registered practical nurse (RPN), assesses joints, pain, function and mood, teaches about medicines and self-management, and monitors for infection and side effects. In Ontario, "administering a substance by injection" is a controlled act authorized to both RNs and RPNs when there is an order, so either may give methotrexate or a biologic injection and teach self-injection (College of Nurses of Ontario [CNO], 2025). Using CNO's Scope of Practice standard, the nurse needs the **authority** (the controlled act is within the nurse's legislated scope, and there is an order), the **competence** (the knowledge, skill and judgment for the specific product and device) and a **context** whose policies and resources support the activity. An employer may, for example, limit intravenous biologic infusions to nurses with infusion education in a clinic that is equipped to manage reactions; an employer may narrow, but never widen, a nurse's scope.

Injections into joints are usually done by physicians or nurse practitioners (NPs), not by nurses in most settings; employer policy applies. Recognizing danger is everyone's job. A nurse who notices possible GCA, a hot joint with fever, a severe infection in a person on a biologic, or chest pain or leg swelling in a person on a JAK inhibitor acts at once and escalates. An RPN consults the RN or the prescriber as the person's needs change. Employer policy and province or territory matter, and CNO's revised Scope of Practice and Medication standards take effect March 1, 2027 (CNO, 2026).

Chapter 34 Summary

34.1 Joints, Inflammation and Arthritis in Canada

- Synovial joints rely on smooth cartilage and a synovial lining that makes lubricating fluid; arthritis is broadly non-inflammatory (mainly osteoarthritis) or inflammatory (such as rheumatoid arthritis and gout).
- About 6 million people in Canada, or 1 in 5 adults, report arthritis; in one Alberta study, rheumatoid arthritis affected about three times as many First Nations residents, who had fewer specialist visits.
- Assessment covers onset, pattern, morning stiffness, pain, whole-body symptoms and function; morning stiffness of 30 minutes or more suggests inflammatory arthritis.
- On darker skin tones, the nurse relies on warmth, swelling and tenderness compared with the other side, not on redness alone.

- A single hot, swollen, painful joint is treated as septic arthritis until proven otherwise, even without fever; the nurse reports it at once, and fluid is aspirated before antibiotics.

34.2 Osteoarthritis

- Osteoarthritis, the most common arthritis in Canada, is a progressive disease of the whole joint; about 3.9 million adults had diagnosed OA in 2016–2017.
- Pain is worse with use and morning stiffness is brief; diagnosis rests on symptoms and examination, and imaging is often not needed.
- Education, structured exercise and, for knee OA, weight management are core treatments; movement, not rest, protects the joint.
- Topical NSAIDs are strongly recommended for knee OA; oral NSAIDs are not recommended with cardiovascular disease or frailty; the OARSI guideline advises against acetaminophen (conditionally) and opioids (strongly).
- Before an oral NSAID, the nurse checks kidney function, blood pressure, fluid status, bleeding and the medication list, with extra care in older adults.

34.3 Rheumatoid Arthritis

- Rheumatoid arthritis is an autoimmune synovitis that usually affects the same small joints on both sides, with long morning stiffness, fatigue and possible effects on the eyes, lungs and heart.
- Early and equitable access to rheumatology care matters; persistent joint swelling for 6 weeks or more warrants urgent referral.
- Treat-to-target aims for remission or minimal disease activity, starting with methotrexate and changing treatment if the response is not good enough after 3 to 6 months.
- Methotrexate for RA is taken once a week on a named day; daily use by mistake has caused deaths, so nurses check every order at reconciliation, hold and clarify any daily order, and teach with a calendar.
- Teaching covers folic acid as ordered, regular blood tests, no alcohol, reporting fever, sore throat, mouth sores, cough or bleeding, and planning any pregnancy with the rheumatologist.
- Joint protection, energy conservation, splints, therapy, mental health support and help with work are part of nursing care.

34.4 Gout

- Gout is caused by monosodium urate crystals deposited when urate levels stay high; flares bring sudden pain, swelling and warmth, often at the base of the big toe.
- In 2016–2017, about 681,000 people in Canada aged 20 and older (2.4%) had diagnosed gout or another crystal arthritis, with higher rates in males and with age.
- Flares are treated early with colchicine, an NSAID or a corticosteroid; colchicine toxicity begins with stomach and bowel symptoms, and drug interactions are checked.
- The US guideline recommends urate-lowering therapy, usually allopurinol, raised step by step to keep serum urate below 360 µmol/L, with flare prevention for 3 to 6 months at the start.
- A new hot joint with fever is reported promptly, because septic arthritis must be ruled out.

34.5 Lupus and Other Connective Tissue Disorders

- SLE is a multi-organ autoimmune disease that affects women far more than men; in a Canadian cohort, low income, not ethnicity, predicted organ damage.
- Lupus nephritis is often silent at first and is found through urine protein, creatinine and blood pressure; fever may be a flare or an infection.
- EULAR recommends hydroxychloroquine for nearly everyone with SLE, with eye examinations before and at least yearly during treatment, sun protection and the lowest corticosteroid dose possible.
- Systemic sclerosis causes Raynaud phenomenon and organ fibrosis; Sjögren disease causes dry eyes and mouth; PMR causes shoulder and hip stiffness in people 50 and older.

- Giant cell arteritis is an emergency: a new headache, scalp tenderness, jaw pain on chewing or any vision change needs same-day escalation; EULAR (2025) advises urgent referral and corticosteroids without delay when suspicion is strong.

34.6 Medicines for Inflammatory Arthritis

- DMARDs include conventional drugs (methotrexate once weekly), biologics and JAK inhibitors; biosimilars are highly similar, less expensive versions of biologics.
- In 2022, Health Canada announced updated labelling for all JAK inhibitors warning of serious heart-related problems, fatal blood clots and cancer, with particular caution for older adults, smokers and people with heart, clot or cancer risk factors.
- Screening for TB infection and hepatitis B, and vaccines given before treatment, precede biologics and JAK inhibitors; live vaccines are avoided.
- Long-term corticosteroids are never stopped suddenly; immunosuppressive medicines are held or continued only as the prescriber directs.
- Provincial and territorial plans, private insurance and NIHB shape access to these medicines.

34.7 Living Well With Chronic Arthritis

- Arthritis Society Canada reports arthritis as a leading cause of disability and work limitation in Canada, and people with arthritis are more likely to have a mood disorder such as depression.
- The nurse assesses pain, fatigue, sleep and mood, and supports paced physical activity.
- EULAR recommends nurse-led education, consultations, telephone and virtual access, psychosocial support and self-management support.
- Rural, remote and northern communities and Indigenous people face access barriers; culturally safe care and help with coverage are part of nursing care.

Key Terms (41)

anti-CCP antibodies: Antibodies to cyclic citrullinated peptides; a blood test that is more specific for rheumatoid arthritis than rheumatoid factor, although a negative result does not rule the disease out.

arthritis: Inflammation of a joint; used as a general term for many conditions that affect joints and the tissues around them.

articular cartilage: The smooth, firm tissue covering the ends of bones in a synovial joint, which lets them glide and spreads the load.

autoimmune disease: A disease in which the immune system attacks the body's own tissues.

biologic: A medicine made in living cells, usually a protein such as an antibody, that blocks one specific part of the immune response.

biosimilar: A highly similar and generally less expensive version of an originator biologic, approved by Health Canada after showing no meaningful differences in safety and effectiveness.

C-reactive protein (CRP): A protein the liver makes during inflammation; a non-specific blood marker of inflammation from any cause.

corticosteroid: A medicine related to the body's own cortisol that quickly reduces inflammation and immune activity; long-term use suppresses the body's cortisol production.

disease-modifying antirheumatic drug (DMARD): A medicine that slows or stops the immune process that damages joints, rather than only relieving symptoms.

energy conservation: Planning, pacing and resting before exhaustion to manage fatigue in chronic arthritis.

erythrocyte sedimentation rate (ESR): A blood test of how quickly red blood cells settle in a tube; it rises with inflammation but is not specific.

flare: A period when symptoms of a chronic inflammatory disease suddenly return or worsen.

giant cell arteritis: A vasculitis of large arteries, including those of the head, in adults older than 50 that can cause permanent vision loss if not treated at once.

gout: A form of inflammatory arthritis caused by deposits of monosodium urate crystals in and around joints and in other tissues.

gout flare: A sudden attack of pain, swelling and warmth in a joint caused by the immune response to urate crystals.

JAK inhibitor: An oral targeted synthetic DMARD that blocks Janus kinase enzymes inside immune cells, interrupting signals from many inflammatory messengers.

joint protection: Ways of doing daily tasks that reduce strain on painful joints, such as using larger joints, avoiding tight gripping and using aids.

lupus nephritis: Inflammation of the kidneys caused by systemic lupus erythematosus.

methotrexate: The most commonly used disease-modifying drug for rheumatoid arthritis, taken once a week on a named day; daily use by mistake has caused fatal toxicity.

morning stiffness: Joint stiffness after waking; lasting 30 minutes or more suggests inflammatory arthritis, while osteoarthritis stiffness usually eases in less than 30 minutes.

nonsteroidal anti-inflammatory drug (NSAID): A medicine that reduces pain and inflammation; risks include stomach bleeding, kidney injury, fluid retention and cardiovascular events.

osteoarthritis (OA): A progressive disease of the whole joint in which cartilage and underlying bone break down; the most common type of arthritis in Canada.

pain sensitization: A state in which the nervous system amplifies pain signals, so pain is felt more strongly than tissue changes alone would explain.

photosensitivity: An abnormal skin reaction, such as a rash, after exposure to sunlight.

polymyalgia rheumatica: An inflammatory condition of adults aged 50 and older that causes aching and stiffness of the shoulders and hips.

Raynaud phenomenon: Episodes in which small arteries of the fingers or toes spasm in cold or stress, so that the skin changes colour and may feel numb or painful.

rheumatoid arthritis (RA): A chronic autoimmune disease that inflames the joint lining, usually in the same joints on both sides of the body, and can affect other organs.

rheumatoid factor (RF): An antibody often present in rheumatoid arthritis; it also appears in some other conditions and is absent in some people with RA.

self-management: The day-to-day skills a person uses to live with a chronic condition, such as taking medicines, pacing activity, solving problems and knowing when to seek help.

septic arthritis: Infection inside a joint; a single hot, swollen, painful joint is treated as septic arthritis until proven otherwise.

Sjögren disease: A systemic autoimmune disease marked by dry eyes and dry mouth, with fatigue, pain and sometimes involvement of other organs.

synovial joint: A freely movable joint in which cartilage-covered bone ends sit inside a capsule lined with synovium and filled with synovial fluid.

synovitis: Inflammation of the synovium, the lining of a synovial joint.

synovium: The inner lining of a joint capsule, which makes the fluid that lubricates the joint and nourishes the cartilage.

systemic lupus erythematosus: A chronic autoimmune disease in which antibodies against the body's own cell parts cause inflammation in many organs.

systemic sclerosis: A rare autoimmune disease that damages small blood vessels and causes thickening and scarring of the skin and internal organs.

tophus: A firm, chalk-like deposit of urate crystals under the skin, often on the ear, elbow or finger pads (plural tophi).

treat-to-target: An approach that sets a goal such as remission, measures disease activity regularly and adjusts treatment until the goal is reached.

urate-lowering therapy: A long-term medicine, such as allopurinol, that lowers the body's urate level to dissolve crystals and prevent gout flares.

uric acid: A waste product of purine breakdown that the kidneys remove; a high blood level can lead to urate crystal deposits.

vasculitis: Inflammation of the walls of blood vessels.

Licensure Review & Clinical Judgment Questions (40)

Questions tagged **[Core]** apply to all nursing students (NCLEX-RN, REx-PN, and CPNRE). Questions tagged **[RN]** draw on *Going Deeper* content.

Case: Ingrid Solberg (Questions 1–4): Ingrid Solberg, 58, was diagnosed with rheumatoid arthritis three weeks ago. Today, at a community rheumatology clinic in Ontario, she is starting oral methotrexate once weekly, with folic acid as ordered. She works full time as a bank teller, lives with her husband and mentions that she usually has a glass of wine with dinner. The RPN is providing her teaching.

1. [CORE] Which statement by Ms. Solberg shows that she understands how to take methotrexate?

a. "I'll take my methotrexate tablets every morning with breakfast, because a routine will help me remember them."

b. "I'll take my methotrexate tablets on Saturdays only, and I'll mark each dose on the calendar on my fridge."

c. "If I forget my methotrexate on my usual day, I'll take two days' worth together the next morning to catch up."

d. "I'll take my methotrexate tablets on any day my hands feel stiff and swollen, but never more than once a day."

Answer: b — For rheumatoid arthritis, methotrexate is taken once a week on the same named day, and a calendar is a recommended way to track doses (section 34.3, Nursing Care and Medicines). Option a describes daily use, the error that has caused fatal toxicity. Option c doubles the dose; a missed dose is discussed with the pharmacist or prescriber, not made up on her own. Option d makes the medicine symptom-driven and could lead to daily use; methotrexate works by steady weekly dosing, not as a pain reliever.

2. [CORE] Ms. Solberg asks why she also has to take folic acid. Which response by the RPN is accurate?

a. "Folic acid makes the methotrexate work faster on your joints, so you will feel better within the first few days."

b. "Folic acid takes the place of methotrexate on the days in between, so the treatment keeps working all week long."

c. "Folic acid protects your bones from thinning, which is the most common problem people have when taking methotrexate."

d. "Folic acid may reduce some side effects of methotrexate, such as mouth sores and stomach upset, so take it as ordered."

Answer: d — According to the Canadian monograph, folic or folinic acid may lessen some methotrexate side effects, such as mouth sores and stomach upset, and folic acid is taken exactly as the prescriber orders (section 34.3, Nursing Care and Medicines). Option a is wrong; folic acid does not speed the effect on the joints. Option b is wrong; folic acid is not a substitute for methotrexate. Option c is wrong; bone thinning is not the purpose of folic acid with methotrexate.

3. [CORE] Ms. Solberg says, "I usually have a glass of wine with dinner. Is that still okay?" Which response by the RPN is best?

a. "The monograph says not to drink alcohol with methotrexate. Your regular blood tests will include liver tests to check for harm."

b. "One glass of wine with dinner is fine, as long as you avoid drinking any alcohol on the same day that you take your weekly dose."

c. "Alcohol is only a concern with methotrexate if you already have liver disease, so you can keep your usual routine."

d. "Wine is safer than beer or spirits with methotrexate, so you can switch to wine if you want to have a drink."

Answer: a — The Canadian monograph lists alcohol use with methotrexate as contraindicated and tells patients not to drink alcohol; liver tests are part of the regular monitoring schedule (section 34.3, Nursing Care and Medicines). Options b and c give permission the monograph does not support. Option d is wrong; the type of alcohol does not change the caution.

4. [CORE] Two months later, Ms. Solberg phones the clinic. She has a temperature of 38.4 °C, a sore throat and new sores in her mouth. Her weekly dose is due tomorrow. Which action should the RPN take?

a. Advise her to take her usual dose tomorrow and to gargle with warm salt water until the sore throat passes.

b. Advise her to double her folic acid for the rest of the week and to call back if she is not better by then.

c. Notify the rheumatologist or NP today, so that she is assessed and the prescriber decides about tomorrow's dose.

d. Advise her to stop taking methotrexate permanently, because these symptoms show that she cannot safely take it again.

Answer: c — Fever, sore throat and mouth sores can signal infection or methotrexate toxicity and must be reported promptly; decisions about holding or continuing a dose belong to the prescriber (section 34.3, Nursing Care and Medicines). Option a delays assessment and gives a dose that may be unsafe. Option b changes a medicine without an order and delays care. Option d is a decision the RPN cannot make alone, and stopping permanently may not be needed.

5. [CORE] A nurse is taking a history from an adult with joint pain. Which finding most suggests an inflammatory arthritis such as rheumatoid arthritis?

a. Knee pain that worsens on stairs and eases after the person sits and rests for a while.

b. Stiffness in the hip that lasts about 10 minutes after getting out of bed each morning.

c. Stiffness in both hands that lasts about 90 minutes each morning, with swelling of the knuckles.

d. Grinding in one knee during deep squatting, with no visible swelling and no stiffness in the morning.

Answer: c — Morning stiffness lasting 30 minutes or more, with swelling in the same joints on both sides, suggests inflammatory arthritis (section 34.1, Assessing the Person With Joint Symptoms). Options a, b and d describe pain with use, brief stiffness and crepitus, which are typical of osteoarthritis.

6. [CORE] A nurse is assessing a swollen wrist in a patient with dark skin. Which approach is best for detecting inflammation?

a. Compare warmth, swelling and tenderness with the other wrist, using the back of the hand to feel for warmth.

b. Look for bright redness over the joint, because redness is the most reliable sign of inflammation on all skin tones.

c. Record that no inflammation is present if the skin over the joint looks the same colour as the surrounding skin.

d. Ask the patient to rate the pain only, because swelling and warmth cannot be assessed on darker skin tones.

Answer: a — Redness can be hard to see on darker skin, so the nurse also checks warmth, swelling and tenderness and compares them with the same joint on the other side (section 34.1, Assessing the Person With Joint Symptoms). Option b relies on colour alone. Option c could miss inflammation. Option d is wrong; warmth and swelling can be assessed on every skin tone.

7. [CORE] An RPN is caring for a 74-year-old man on a medical unit. This morning his left knee became hot, swollen and very painful, and he cannot bend it. His temperature is 37.6 °C. Which action should the RPN take first?

a. Apply a heat pack to the knee and encourage gentle range-of-motion exercises to reduce the stiffness.

b. Give the as-needed acetaminophen that is ordered and reassess the knee at the end of the shift.

c. Document the findings and wait until the next scheduled assessment to see whether the swelling settles.

d. Report the findings promptly to the RN and the prescriber, because the joint may be infected.

Answer: d — A single hot, swollen, painful joint that develops over a short time is treated as septic arthritis until proven otherwise, even without a high fever, and needs prompt reporting so fluid can be aspirated before antibiotics (section 34.1, Assessing the Person With Joint Symptoms). Option a applies heat to an inflamed joint. Options b and c delay escalation of a possible emergency.

8. [CORE] A 62-year-old woman with knee osteoarthritis asks what will help most. According to the OARSI guideline, which treatment is part of the core plan for everyone with knee osteoarthritis?

a. An oral opioid at bedtime, so that pain does not interrupt her sleep at night.

b. Education about arthritis and a structured exercise program, with weight management if needed.

c. Bed rest for several days during each flare, so that the cartilage in the knee has enough time to heal fully.

d. Regular joint injections every few weeks, so that the inflammation in the knee stays low.

Answer: b — The OARSI guideline names arthritis education and a structured land-based exercise program, which may be combined with dietary weight management, as core treatments for knee osteoarthritis (section 34.2, Care and Self-Management). Option a is strongly recommended against. Option c is wrong; movement, not rest, is advised, with gentle range of motion during flares. Option d is not a core treatment; injections are conditionally recommended and are not given routinely every few weeks.

9. [CORE] A 70-year-old man with knee osteoarthritis has heart failure and had a heart attack two years ago. He asks which medicine he could use for knee pain. According to the OARSI guideline, which option is recommended for people with cardiovascular disease?

a. Oral naproxen taken regularly with meals, because food reduces the risk to the heart.

b. Oral celecoxib, because a COX-2 inhibitor is safer for the heart than other NSAIDs.

c. A topical NSAID applied to the knee, because little of the drug reaches the bloodstream.

d. An oral opioid, because opioids do not affect the heart or blood pressure in older adults.

Answer: c — The OARSI guideline strongly recommends topical NSAIDs for knee osteoarthritis, including in people with cardiovascular conditions, and does not recommend oral NSAIDs for them; only a small amount of a topical NSAID is absorbed (section 34.2, Care and Self-Management). Options a and b are oral NSAIDs, which raise cardiovascular risk and can worsen heart failure. Option d is strongly recommended against for osteoarthritis.

10. [CORE] A patient with hip osteoarthritis says, "When my hip is sore, I stay in bed for the whole day so I don't wear it out." Which response by the nurse is best?

a. "Long rest tends to worsen stiffness and weakness. Gentle movement, even on a sore day, helps protect your hip."

b. "Resting in bed whenever it hurts is a good idea, because every single movement wears away a little more of the cartilage."

c. "Staying in bed is fine for now, and you can start exercising once your hip has stopped hurting completely."

d. "Resting is the main treatment for osteoarthritis, so you should limit your walking to short trips at home."

Answer: a — Movement, not rest, protects joints in osteoarthritis; during flares, gentle range-of-motion exercise continues (section 34.2, Care and Self-Management; Patient Education box). Options b, c and d all encourage prolonged rest, which worsens stiffness and weakness and delays the core treatment.

11. [CORE] A nurse is about to give the first dose of oral naproxen to a hospitalized adult with osteoarthritis. Which findings should the nurse report to the prescriber before giving the dose? Select all that apply.

a. Serum creatinine has risen from 78 to 121 µmol/L since admission.

b. The patient had a black, tarry stool this morning.

c. The patient has heart failure, and new ankle swelling and a weight gain of 2 kg are noted.

d. The patient rates knee pain at 6 out of 10 when walking.

e. The patient takes a daily multivitamin at home.

f. The patient takes warfarin.

Answer: a, b, c, f — A rising creatinine suggests kidney injury, which NSAIDs can worsen; black stools suggest bleeding; fluid retention in heart failure can be worsened by NSAIDs; and anticoagulants raise the risk of serious bleeding (section 34.2, Care and Self-Management). Option d is the reason for the medicine, not a reason to hold it. Option e is not a known NSAID risk.

12. [CORE] A patient with knee osteoarthritis asks how to use heat and cold at home. Which instruction is accurate?

a. "Apply heat to the knee whenever it is hot and swollen, because the warmth helps draw the swelling out of the joint."

b. "Use heat only, because cold packs can damage cartilage and make osteoarthritis worse over time."

c. "Use cold packs only at night, and never use heat on the knee, because heat speeds up joint damage."

d. "Cold packs may relieve swelling and brief pain; heat may relieve stiffness but is not put on an inflamed joint."

Answer: d — Cold packs may relieve swelling and brief pain, and heat may relieve stiffness, but heat is not used on an inflamed joint (section 34.2, Care and Self-Management). Option a applies heat to an inflamed joint. Options b and c contain false claims about cartilage damage.

13. [CORE] Which presentation is most typical of rheumatoid arthritis?

a. Pain and grinding in one knee that worsen after a day of gardening and ease overnight.

b. Swelling and tenderness of the knuckles and wrists of both hands, with long morning stiffness and fatigue.

c. Sudden, severe pain and swelling in one big toe that began during the night after a large meal with several drinks.

d. Pain in the lower back that radiates down one leg after lifting a heavy box at work.

Answer: b — Rheumatoid arthritis typically affects the same small joints on both sides, with morning stiffness of 30 minutes or more and whole-body symptoms such as fatigue (section 34.3, What Happens in Rheumatoid Arthritis). Option a suggests osteoarthritis. Option c suggests a gout flare (section 34.4). Option d suggests a back injury.

14. [CORE] A patient newly diagnosed with rheumatoid arthritis asks what "treat-to-target" means. Which explanation is accurate?

a. "Your treatment stays the same for at least two years before the rheumatologist decides whether it is working."

b. "Medicines are given only when your joints flare, and stopped as soon as the swelling in your joints goes down."

c. "You and your team set a goal, such as remission, measure your disease regularly and adjust treatment until you reach it."

d. "Your rheumatologist chooses the strongest medicine available on the very first day, so that no changes are needed later on."

Answer: c — Treat-to-target means setting a goal of remission or minimal disease activity, measuring disease activity regularly and changing treatment until the goal is met, through shared decisions (section 34.3, Diagnosis and Treat-to-Target). Option a delays change; the EULAR update adds a biologic if the response is not good enough after 3 to 6 months. Option b describes on-and-off treatment, which does not control the disease. Option d is wrong; treatment starts with methotrexate and is adjusted over time.

15. [CORE] A patient with rheumatoid arthritis has painful, swollen hands and severe fatigue. Which teaching about joint protection and energy conservation is appropriate?

a. "Carry bags over your forearm instead of gripping them, and plan rest breaks before you become exhausted."

b. "Push through tiredness to finish all your housework in the morning, while your energy is at its peak."

c. "Grip objects as tightly as you can, because strengthening your fingers will prevent joint damage."

d. "Avoid using any aids such as jar openers, because they make your hand muscles weaker over time."

Answer: a — Joint protection reduces strain on inflamed joints and uses assistive devices, and energy conservation means pacing and resting before exhaustion (section 34.3, Nursing Care and Medicines). Option b leads to exhaustion. Option c strains inflamed joints. Option d is wrong; aids such as jar openers protect joints.

16. [CORE] During admission medication reconciliation, an RPN notices that a patient's home methotrexate for rheumatoid arthritis has been ordered "once daily." The patient's blister pack shows one dose each Saturday. Which action should the RPN take?

a. Give the dose as ordered, because the prescriber may have changed the schedule while the patient was in emergency.

b. Change the order to weekly on the medication record and document that the error was corrected.

c. Give half of the dose today and the rest on Saturday, so that the patient receives a safe amount this week.

d. Hold the dose, report the discrepancy to the RN and prescriber, and involve the pharmacist to clarify the order.

Answer: d — Daily use of weekly methotrexate has caused fatal toxicity. Any nurse who finds a discrepancy at medication reconciliation holds the dose and clarifies the order with the prescriber and pharmacist; the RPN also informs the RN (section 34.3, Nursing Care and Medicines; Practice Story; section 1.3). Option a risks giving a dangerous dose. Option b is outside the nurse's authority; nurses do not change orders themselves. Option c changes the dose without an order.

17. [CORE] A 29-year-old woman with rheumatoid arthritis has taken methotrexate for a year. She tells the nurse she would like to become pregnant next year. Which response is best?

a. "You can stop your birth control now, because methotrexate only affects a pregnancy in the first few days."

b. "Talk with your rheumatologist well before you stop birth control, because methotrexate can harm a pregnancy."

c. "Stop your methotrexate the week you decide to try to conceive, and restart it once you know you are pregnant."

d. "Methotrexate is a concern only if your partner takes it, so you can plan a pregnancy without changing anything."

Answer: b — Methotrexate can cause fetal death and birth defects; pregnancy is avoided if either partner takes it, and published advice on the waiting time after stopping ranges from 3 months to one year, so planning with the rheumatologist is essential (section 34.3, Nursing Care and Medicines). Options a, c and d are all unsafe or false.

18. [RN] An adult has had swelling in several small joints of both hands for 8 weeks. Results: RF negative; anti-CCP antibodies more than three times the upper limit of normal; CRP raised. Which interpretation by the RN is most accurate?

a. The results support rheumatoid arthritis, because anti-CCP is highly specific, and a negative RF does not rule the disease out.

b. The results rule out rheumatoid arthritis, because a positive rheumatoid factor is required before the diagnosis can be made.

c. The results confirm an infection, because a raised CRP is specific to bacterial infection rather than to joint inflammation.

d. The results point to osteoarthritis, because anti-CCP antibodies are a marker of cartilage breakdown in the small joints.

Answer: a — Anti-CCP is more specific for rheumatoid arthritis than RF, many people with RA are RF-negative, and a raised CRP reflects inflammation of any cause (section 34.1, Going Deeper; Table 34.2). Option b is wrong; RF is not required. Option c is wrong; CRP is not specific to infection. Option d is wrong; anti-CCP is an autoimmune antibody, and no blood test diagnoses osteoarthritis.

19. [RN] A 79-year-old woman with chronic kidney disease takes furosemide and ramipril. She asks the RN for oral ibuprofen for knee osteoarthritis pain. Which response is best?

a. "Ibuprofen is safe with your kidney disease if you take it with food and drink plenty of water."

b. "Ibuprofen is a safe choice for you, because it is sold without a prescription at every pharmacy."

c. "Oral ibuprofen could harm your kidneys with these medicines. I'll ask your prescriber about a skin gel."

d. "You should take acetaminophen and ibuprofen together, because that combination protects your kidneys."

Answer: c — Older age, kidney disease, diuretics and ACE inhibitors all raise the risk of NSAID-related kidney injury; a topical NSAID delivers little drug to the blood and is the guideline's strongly recommended medicine for knee osteoarthritis (section 34.2, Care and Self-Management; Lifespan Considerations box; section 27.3). Option a does not remove the kidney risk. Option b confuses over-the-counter availability with safety. Option d is wrong; acetaminophen does not protect the kidneys.

20. [RN] A 55-year-old man with rheumatoid arthritis who takes methotrexate is admitted with a right knee that is hot, much more swollen than his other joints and too painful to bend. His temperature is 38.2 °C and his heart rate is 108 beats/min. His other joints are at their usual level of stiffness. Which hypothesis should the RN treat as the priority?

a. A flare of rheumatoid arthritis, because a flare often begins in one large joint and causes a fever.

b. Osteoarthritis of the knee, because long-standing rheumatoid arthritis often turns into osteoarthritis.

c. Methotrexate toxicity, because high fever and swelling of one knee are the first signs of toxicity.

d. Septic arthritis, because one hot joint out of proportion to the others, with fever, needs urgent assessment.

Answer: d — A single hot, swollen joint out of proportion to the person's other joints, with fever and a fast heart rate in someone whose immune defences are lowered, is treated as septic arthritis until proven otherwise; fluid is aspirated before antibiotics, and the RN watches for sepsis (section 34.1, Assessing the Person With Joint Symptoms; section 4.6). Option a is less likely and would delay urgent care. Option b does not explain the fever. Option c is wrong; mouth sores are often the first sign of toxicity, and toxicity does not explain one hot joint.

Case: Leila Haddad (Questions 21–26): Leila Haddad, 34, has systemic lupus erythematosus treated with hydroxychloroquine and daily prednisone. She is admitted to a medical unit with 2 days of fever and sharp left-sided chest pain that is worse when she breathes in. She says she stopped her hydroxychloroquine a month ago because she "felt fine." Vital signs: temperature 38.4 °C, heart rate 108, respiratory rate 22, blood pressure 148/94 mm Hg (her usual is 118/74 mm Hg) and oxygen saturation 95% on room air. Both ankles have pitting edema, and her weight is up 3 kg in a week. Urinalysis shows 3+ protein, which was negative at her last clinic visit. Her creatinine is 142 µmol/L (68 µmol/L 3 months ago). Over the first 24 hours, her intake is 2,100 mL and her urine output is 650 mL.

21. [CORE] Which findings should the nurse recognize as cues that need follow-up? Select all that apply.

a. Temperature of 38.4 °C

b. Chest pain that is worse when she breathes in

c. Blood pressure of 148/94 mm Hg

d. New 3+ protein in the urine

e. Creatinine of 142 µmol/L, up from 68 µmol/L

f. Oxygen saturation of 95% on room air

g. She is 34 years old and works as a teacher

Answer: a, b, c, d, e — Fever in a person taking prednisone may mean infection or a lupus flare and needs follow-up (a; section 34.5). Chest pain that worsens with breathing suggests serositis, a lupus feature, though other causes must be considered (b). A blood pressure well above her usual, new protein in the urine and a doubled creatinine point to kidney involvement (c, d, e; section 34.5; Chapter 27). An oxygen saturation of 95% on room air is within a normal range (f). Her age and job are background, not findings that need follow-up (g).

22. [CORE] Which explanation best links Ms. Haddad's blood pressure, ankle edema, proteinuria and rising creatinine?

a. Dehydration from her fever has reduced blood flow to her kidneys, and the ankle swelling reflects a low protein intake.

b. Daily prednisone has caused fluid retention, which raises her blood pressure and pushes protein out into her urine.

c. Lupus nephritis, inflammation of the kidneys from SLE, is causing protein loss, fluid retention and falling kidney function.

d. Pericarditis has led to heart failure, which explains her ankle edema, her 3 kg weight gain, her higher blood pressure and her creatinine.

Answer: c — New proteinuria, edema, higher blood pressure and a rising creatinine together fit lupus nephritis, a serious form of SLE that is found by checking urine, creatinine and blood pressure (c; section 34.5). Dehydration does not cause edema, weight gain or heavy proteinuria (a). Corticosteroids can raise blood pressure, but they do not cause new heavy proteinuria or a doubled creatinine (b). She has no findings of heart failure, such as low oxygen saturation or crackles, and heart failure does not explain heavy proteinuria (d).

23. [RN] The team is considering both an infection and a lupus flare as causes of Ms. Haddad's fever. Which statement best guides the nurse's priorities?

a. Fever in SLE is almost always a sign of a flare, so the nurse should ask the prescriber to increase her prednisone dose before any other tests are done tonight.

b. Infection and a flare can look alike in a person taking prednisone, so the nurse reports promptly so that infection can be looked for before immunosuppression is increased.

c. Daily prednisone protects her against infection, so an infection is unlikely, and the nurse should focus all of the assessment on her kidney findings for now.

d. Her chest pain is most likely a pulmonary embolism, so the nurse should give a dose of anticoagulant right away and leave the question of her fever until the medical team rounds in the morning.

Answer: b — In a person taking corticosteroids, infection and a lupus flare can look alike, and giving more immunosuppression to someone with an untreated infection can be dangerous, so infection is looked for first (b; section 34.5; Chapter 4). Assuming a flare without testing could miss an infection (a). Corticosteroids raise, not lower, infection risk (c; section 34.6). The team does consider other causes of chest pain, but nurses do not start anticoagulation without an order, and the fever cannot be set aside (d).

24. [CORE] Which plan best supports monitoring of Ms. Haddad's fluid balance?

a. Weigh her daily on the same scale at the same time, keep a strict intake and output record, and report output below the ordered limit or further weight gain.

b. Encourage her to drink at least 3 L of fluid each day to flush her kidneys, and record her intake on the bedside sheet each time she finishes a full glass of water.

c. Hold her ordered blood pressure medicines so that her kidneys receive more blood flow, and recheck her blood pressure once at the end of the shift to see whether it has risen.

d. Insert a urinary catheter on the nurse's own judgment so that hourly output can be measured, and remove it once her creatinine returns to her usual level.

Answer: a — Daily weights and accurate intake and output show fluid retention and falling urine output, which the nurse reports according to the orders (a; section 34.5; Chapter 3). Extra fluid could worsen edema when kidney function is falling; fluid intake follows the prescriber's order (b). Blood pressure medicines are not held without an order, and rising blood pressure in lupus nephritis needs treatment (c). A urinary catheter needs an order and adds infection risk, and it is not routine for this purpose (d).

25. [CORE] The nurse calls the internal medicine resident. Which report best follows SBAR?

a. "Ms. Haddad in bed 4 has lupus and a fever. Can you order some acetaminophen and maybe an antibiotic for her?"

b. "I'm calling about Ms. Haddad. She stopped her hydroxychloroquine and her lupus is flaring, so she probably needs more prednisone tonight."

c. "Ms. Haddad's creatinine is 142. Is that high for her? She also has some ankle swelling, but she has been lying in bed all day."

d. "Ms. Haddad, 34, with SLE on prednisone, has a temperature of 38.4, pleuritic chest pain, BP 148/94 from 118/74, new 3+ proteinuria, creatinine 142 from 68 and 650 mL of urine in 24 hours. I'm concerned about infection and kidney involvement. Please assess her within the hour."

Answer: d — Option d gives the situation, background, an assessment with specific values and the nurse's concern, and a clear request with a time frame (d; section 34.5; Chapter 6). Option a asks for treatment without data or a concern (a). Option b offers a conclusion about a flare without data and leaves out the possibility of infection (b). Option c gives one value without context and dismisses a finding that matters (c).

26. [CORE] Before discharge, Ms. Haddad's infection screen is negative, and she has started treatment for lupus nephritis. Which statement shows that her teaching has been effective?

a. "Once my kidney tests are back to normal, I can stop taking the prednisone on my own, because I really don't like the way it makes me feel."

b. "My eyes are fine right now, so I can skip the eye checks for hydroxychloroquine until I notice a problem with my vision."

c. "I'll take my hydroxychloroquine every day even when I feel well, and I'll call if my ankles swell or I pass less urine."

d. "Lupus doesn't seem to affect my skin, so I don't need to worry about sunscreen or covering up when I'm outside this summer."

Answer: c — Taking hydroxychloroquine every day, even in remission, and reporting signs of kidney involvement show understanding (c; section 34.5). Stopping prednisone suddenly after long-term use can cause adrenal crisis, and changes are made with the prescriber (a; section 34.6). Eye examinations are needed before and at least yearly during long-term hydroxychloroquine, because the drug can damage the retina (b). Lupus is photosensitive, and EULAR advises people with SLE to avoid sun exposure in particular (d).

27. [CORE] Which description best fits a gout flare?

a. Sudden, severe pain, swelling and warmth in the joint at the base of the big toe that came on over a few hours

b. Gradual stiffness in both knees that is worse after activity and eases after a few minutes of rest

c. Aching and stiffness in both shoulders and hips each morning for more than an hour in a person older than 50

d. Swelling in the small joints of both hands, with morning stiffness each day that has lasted for several months now

Answer: a — A gout flare comes on over a few hours, with a swollen, warm and very painful joint, commonly the first metatarsophalangeal joint (a; section 34.4). Gradual stiffness that eases with rest suggests osteoarthritis (b; section 34.2). Shoulder aching and stiffness in an older adult suggests polymyalgia rheumatica (c; section 34.5). Symmetric small-joint swelling with long morning stiffness suggests rheumatoid arthritis (d; section 34.3).

28. [CORE] A 70-year-old man with gout takes colchicine to prevent flares. Which teaching is most important?

a. Take an extra dose of colchicine whenever a joint begins to ache, since the medicine works best when it is given early in a flare.

b. Stop colchicine whenever you start a new blood pressure medicine, since the two kinds of medicine always interact with each other.

c. Expect some mild diarrhea while taking colchicine, and keep taking it every day until the end of the prescription.

d. Tell your prescriber and pharmacist that you take colchicine before starting any new medicine, such as an antibiotic.

Answer: d — Some medicines, such as clarithromycin, can raise colchicine to dangerous levels, and older adults face higher risk, so every new prescription must be checked (d; section 34.4). Extra doses are taken only as prescribed, and higher doses increase toxicity (a). Not all blood pressure medicines interact, and stopping is decided with the prescriber (b). Diarrhea can be an early sign of toxicity and is reported, not ignored (c).

29. [CORE] A man newly diagnosed with gout asks whether he will have to give up all meat. Which response by the nurse is best?

a. "Yes. Purines in meat are the cause of gout, so a strict meat-free diet is the main treatment and can replace your medicines."

b. "Limiting alcohol, sweet drinks and purine-rich foods can help, and your medicines will do most of the work of lowering urate."

c. "No. Diet makes no difference to gout at all, so you can eat and drink whatever you like as long as you take your medicine."

d. "Taking a vitamin C supplement every day will lower your urate level enough that you can keep eating and drinking as you do now."

Answer: b — The US guideline suggests limiting alcohol, purine-rich foods and high-fructose corn syrup, alongside medicines that lower urate to the target, and the nurse avoids blaming language (b; section 34.4). A strict diet is not presented as a replacement for urate-lowering therapy (a). Diet and alcohol do matter as part of care (c). The guideline does not support vitamin C supplements (d).

30. [CORE] On day 2 after a bowel resection, a 66-year-old man with a history of gout has a hot, swollen right knee, a temperature of 38.6 °C and a heart rate of 112. What should the nurse do first?

a. Apply ice, raise the knee and give the as-needed analgesic that is ordered, then reassess the knee and his temperature in 4 hours.

b. Ask the patient to stop taking his allopurinol, since restarting it after surgery has probably caused this flare of gout.

c. Report the findings to the prescriber promptly, because the knee could be infected and needs urgent assessment.

d. Encourage the patient to walk on the knee to prevent stiffness, since gout flares settle faster when the joint keeps moving.

Answer: c — A hot joint with fever and a fast heart rate may be septic arthritis, which is an emergency, so the nurse reports it promptly so that the joint can be assessed (c; sections 34.1 and 34.4; Chapter 4). Comfort measures help, but waiting 4 hours could delay treatment of a septic joint (a). Urate-lowering therapy is not stopped without the prescriber's direction, and the cause is not yet known (b). Walking on an acutely inflamed joint is not advised (d).

31. [CORE] A woman with SLE asks how she can lower her risk of a flare this summer. Which response is best?

a. "Protect your skin from the sun with clothing, a hat and sunscreen, since lupus makes the skin sensitive to sunlight."

b. "Spend some time in the sun each day, since the vitamin D you make from sunlight helps to calm the immune system in lupus."

c. "Stop taking your hydroxychloroquine during the summer months, since it makes your skin burn much more easily in the sun."

d. "Avoid all exercise during hot weather, since physical activity is one of the most common triggers for lupus flares."

Answer: a — Lupus is characteristically photosensitive, and EULAR advises people with SLE to avoid sun exposure in particular (a; section 34.5). Sun exposure is something to avoid, not a treatment (b). EULAR advises against stopping hydroxychloroquine (c). Regular exercise is part of EULAR's advice for lupus (d; section 34.7).

32. [CORE] A woman starting long-term hydroxychloroquine for SLE asks why she has been referred to an eye specialist. Which response is accurate?

a. "Hydroxychloroquine causes cataracts in most people who take it, so the specialist will plan your cataract surgery in advance."

b. "The eye check is needed only if you notice blurred vision or other changes in your sight after you start taking the medicine."

c. "Lupus always affects the eyes sooner or later, so the specialist will be treating your lupus rather than checking the drug."

d. "The medicine can damage the retina, so you need an eye exam before you start and at least once a year."

Answer: d — A current Canadian monograph calls for an eye examination before long-term treatment and at least yearly afterward, because hydroxychloroquine can damage the retina (d; section 34.5). Cataract surgery is not planned for people taking this medicine (a). The monograph schedules the checks regardless of symptoms, so they do not wait for vision changes (b). The referral is for medicine safety, not because lupus always involves the eyes (c).

33. [CORE] A man with systemic sclerosis has Raynaud phenomenon. Which teaching is most helpful?

a. Soak your hands in very hot water at the start of each attack so that the narrowed blood vessels open up as quickly as possible.

b. Keep your whole body and hands warm in cold weather, and report any finger sore or a finger that stays pale or dark.

c. Avoid using your hands for any tasks during the winter months, since hand movement is what triggers attacks of Raynaud phenomenon.

d. Expect your fingers to stay white for several hours during each attack, since this is the usual pattern and does not need to be reported.

Answer: b — Cold triggers attacks, so warmth helps, and finger ulcers or a finger that does not regain its colour need prompt care (b; section 34.5; Table 34.3). Very hot water can burn skin with reduced sensation (a). Movement is not the trigger, and avoiding all hand use is not needed (c). Colour returns as blood flow returns; a finger that stays pale or dark is a danger sign (d).

34. [CORE] A woman with Sjögren disease says her mouth is so dry that she has trouble eating. Which suggestion is most appropriate?

a. Suck on hard candies that contain sugar throughout the day to keep the saliva flowing.

b. Rinse with an alcohol-based mouthwash several times a day to keep the mouth clean.

c. Chew sugar-free gum or use a saliva substitute, and keep regular dental visits.

d. Limit fluids with meals so that the small amount of saliva your glands make is not diluted.

Answer: c — Sugar-free gum or lozenges and saliva substitutes ease dryness, and dental care protects teeth, which are at risk when saliva is low (c; section 34.5). Sugar increases the risk of tooth decay in a dry mouth (a). Alcohol-based mouthwash can worsen dryness (b). Sips of fluid with meals help with chewing and swallowing (d).

35. [CORE] A 72-year-old woman with polymyalgia rheumatica calls the clinic. Which findings need same-day assessment for possible giant cell arteritis? Select all that apply.

a. A new headache over one temple

b. Pain in the jaw that starts when she chews

c. Tenderness of the scalp when she brushes her hair

d. Blurred vision in one eye that lasted 5 minutes

e. Shoulder stiffness for 30 minutes in the morning, unchanged for months

f. Mild ache in both knees after an afternoon of gardening

Answer: a, b, c, d — A new headache, jaw pain with chewing, scalp tenderness and any visual symptom can be features of GCA, an emergency that threatens vision, so they need same-day escalation (a, b, c, d; section 34.5). Brief blurred vision is especially urgent, because people with cranial symptoms are at high risk of permanent vision loss and EULAR advises immediate referral. Stable, mild morning stiffness is her usual PMR pattern (e). A knee ache after activity is not a feature of GCA (f).

36. [CORE] A man with rheumatoid arthritis covered by the Ontario Drug Benefit program is told that his originator adalimumab will be changed to a biosimilar. He asks whether the new product will work as well. Which response is best?

a. "Health Canada approves a biosimilar only when it does not differ in any meaningful way in safety or effectiveness, and I'll show you how to use the new pen."

b. "A biosimilar is an exact copy of your current medicine sold under a different name, so nothing about your treatment, your pen or your injection routine will change at all."

c. "A biosimilar is a weaker version of your current medicine, so your rheumatologist will probably need to increase how often you inject it to keep your arthritis controlled."

d. "Switching is entirely your choice, so you can keep taking the original product under the drug plan if you would rather not change."

Answer: a — Health Canada approves a biosimilar only after finding no meaningful difference from the originator in safety or effectiveness, and the nurse teaches the new device (a; section 34.6). A biosimilar is highly similar but not identical, and the device may differ (b). Biosimilars are not weaker versions (c). Under the Ontario policy, coverage of originator adalimumab requires an exemption, so continuing it is not simply the person's choice (d).

37. [CORE] An RPN in a rheumatology clinic is asked to give a patient's first dose of a new subcutaneous biologic using an autoinjector device the RPN has never used. There is an order, and the clinic's policy allows RPNs to give this medicine. What should the RPN do?

a. Decline, because only RNs are authorized to give biologic medicines by injection in Ontario.

b. Give the dose using general injection skills, since the order and clinic policy provide the needed authority.

c. Ask the patient to give the first dose alone, since the patient will be self-injecting at home anyway.

d. Learn the device from the product teaching material or an experienced colleague before giving the dose.

Answer: d — The RPN has the authority (the controlled act and an order) and a supportive context (clinic policy) but must also have the competence for the specific product and device, so the RPN gets the needed education first (d; section 34.7, Scope in Practice box; Chapter 1, section 1.3). Administering a substance by injection is a controlled act authorized to both RNs and RPNs (a). Authority alone is not enough; competence is also needed (b). Teaching self-injection still requires a nurse who knows the device, and the first self-injection is supervised (c).

38. [CORE] A woman with polymyalgia rheumatica has taken prednisone for 10 months. She says, "I feel so much better that I'm going to stop the prednisone tomorrow." Which response by the nurse is best?

a. "That's a good plan, since your symptoms have gone away and long-term prednisone has many side effects you would be glad to avoid."

b. "Please don't stop it suddenly; after months of use, your body needs a gradual taper that your prescriber plans."

c. "Cut your dose in half tomorrow, and stop it completely next week if your shoulders and hips still feel fine by then."

d. "Switch to an anti-inflammatory such as ibuprofen instead, since it treats polymyalgia rheumatica just as well."

Answer: b — Long-term corticosteroids suppress the body's own cortisol production, so stopping suddenly can cause adrenal crisis, and the taper is planned by the prescriber (b; section 34.6; Chapter 23). Stopping suddenly is unsafe (a). The nurse does not invent a taper schedule (c). PMR is treated with corticosteroids rather than NSAIDs (d; section 34.5).

39. [RN] A man with recurrent gout started allopurinol and colchicine prophylaxis 6 weeks ago. He has a flare in his ankle and says, "The allopurinol is making my gout worse, so I'm stopping it." Which response is best?

a. "You're right. Allopurinol should be stopped during every flare and then restarted once the joint has settled down completely."

b. "That suggests you are allergic to allopurinol, so the prescriber will need to switch you to a different urate-lowering medicine."

c. "Flares can happen in the first months of treatment, so keep taking it, treat the flare as planned and let your prescriber know."

d. "A flare means your dose is already too high, so take half of your usual allopurinol dose each day until your next blood test."

Answer: c — Flares can occur in the early months of urate-lowering therapy, which is why the US guideline recommends prophylaxis for 3 to 6 months and supports continuing ULT toward the target (c; section 34.4). Stopping and restarting ULT with each flare delays reaching the urate target (a). A flare is not a sign of allergy; a rash is the warning sign to report (b). Dose changes are made by the prescriber, and the dose is usually raised, not lowered, to reach the target (d).

40. [RN] A 52-year-old woman with rheumatoid arthritis is scheduled to start adalimumab. Which pre-treatment finding should the nurse report to the prescriber before the first dose?

a. A positive interferon-gamma release assay (IGRA), with no cough or other symptoms

b. A raised C-reactive protein level that matches the amount of swelling in her joints

c. A positive rheumatoid factor test on the diagnostic bloodwork done last month

d. An inactivated influenza vaccine given 3 weeks before the planned start date

Answer: a — A positive IGRA suggests TB infection; active TB must be ruled out, and TB infection is treated before a TNF inhibitor starts (a; section 34.6, Going Deeper box). A raised CRP reflects active RA, which is why treatment is starting (b; section 34.1). A positive rheumatoid factor supports the diagnosis and does not delay treatment (c). Giving non-live vaccines before immunosuppression starts is recommended when possible (d).

35 Skin, Wounds and Burns

LEARNING OUTCOMES & COMPETENCY MAPPING

By the end of this chapter, you will be able to:

1. Assess skin accurately on a range of skin tones and prevent moisture damage and skin tears.
2. Assess pressure injury risk, prevent pressure injuries and describe their stages, including deep tissue injury on darker skin.
3. Assess wounds and choose care that matches the cause and the wound's needs, and recognize wound infection.
4. Care for surgical wounds and skin infections, and recognize dehiscence, evisceration and necrotizing infection as emergencies, using the CJMM.
5. Give first aid and early care after a burn, recognize airway threats and support burn recovery.
6. Recognize warning signs of skin cancer and common skin conditions in adults, and teach skin protection.
7. Distinguish RN and RPN roles in skin and wound care using CNO's authority, competence and context.

How the outcomes map to the CNO entry-to-practice competencies

Outcome	RN competency role (CNO, 2019a)	RPN competency category (CNO, 2019b)
1, 2, 3, 4, 5	Clinician; Leader	Foundations of Practice
6	Educator; Advocate	Foundations of Practice
7	Professional; Collaborator	Legal Practice; Collaborative Practice

Introduction

Skin is the body's largest organ and the one nurses see and touch most often. Every bath, turn, dressing change and admission assessment is a chance to notice a problem early: a warm, firm patch over a hip, a torn flap of skin on a forearm, a wound that has stopped getting smaller. Many skin injuries that happen during care can be prevented, and those that do occur heal better when they are found, described and treated early. Because so much of this work happens at the bedside, skin and wound care belongs to every nurse.

This chapter is the book's home for skin, wounds and burns. Section 35.1 reviews how skin works and how to assess it accurately on every skin tone, then covers moisture damage and skin tears. Section 35.2 explains how pressure injuries develop and how to prevent, stage and care for them. Section 35.3 covers wound healing, wound assessment, cleansing, dressings and wound infection. The second half of the chapter turns to surgical wounds and skin infections such as cellulitis (section 35.4), burns (section 35.5), and skin cancer and other common skin conditions (section 35.6).

The chapter builds on earlier ones. Scope of practice for registered nurses (RNs) and registered practical nurses (RPNs) is taught in section 1.3, and the Clinical Judgment Measurement Model (CJMM) in section 1.4. Outside Ontario, practical nurses (PNs) are often called licensed practical nurses (LPNs); this chapter uses "the nurse" unless the roles differ. Inflammation, infection prevention and control (IPAC) and sepsis are in Chapter 4, pain in Chapter 5, and recognizing deterioration and SBAR (Situation, Background, Assessment, Recommendation) communication in Chapter 6. Older adults and frailty are in Chapter 8, nutrition in section 24.1, vascular disease in Chapter 19, the diabetic foot in Chapter 22 and continence in Chapter 28.

35.1 Skin Structure and Assessment

How Skin Works

Skin has three layers (Orsted et al., 2025b). The **epidermis** is the thin outer layer. It has no blood vessels of its own and is fed by diffusion from the layer below. Its outermost cells form a waterproof barrier that is shed and replaced all the time; the whole epidermis renews itself over about 35 to 45 days. Melanocytes in its base make melanin, the pigment that gives skin its colour and absorbs ultraviolet light. The **dermis** lies beneath. It holds collagen and elastic fibres, capillaries, nerve endings, hair follicles, and sweat and oil glands. Small ridges called rete pegs lock the epidermis into the dermis and help the layers resist shear. Below the dermis is the **hypodermis**, or subcutaneous tissue, made mostly of fat. It insulates, cushions and stores energy, but its blood supply is poor, so wounds that reach it heal more slowly (Orsted et al., 2025b; Figure 35.1).

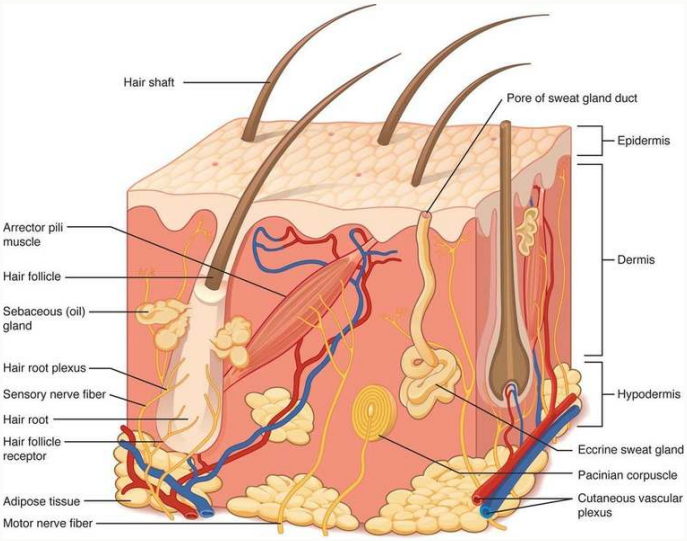

Figure 35.1 Cross-section of human skin showing the epidermal layers, dermal structures (hair follicles, glands, nerve endings, blood vessels) and the deeper subcutaneous hypodermis. (credit: “Figure 5.2, Layers of Skin” by J. Gordon Betts et al./OpenStax, Anatomy and Physiology 2e, CC BY-NC-SA 4.0)

Together these layers protect the body from water loss, chemicals, microorganisms, mechanical force and radiation. Skin also senses touch, pressure, temperature and pain, helps control body temperature through sweating, makes vitamin D and takes part in immune defence (Orsted et al., 2025b).

Skin changes with age. In older adults, the epidermis thins and renews itself about half as fast. The rete pegs flatten, so the layers separate more easily under friction and shear. Collagen falls by about 1% a year and elastin declines, so skin wrinkles and loses its spring. The dermis has fewer blood vessels, the fat layer shrinks, and skin becomes drier and more alkaline, which favours bacterial growth. Older skin also senses light touch and pressure less well. The result is skin that is injured easily, heals slowly and dries out quickly (Orsted et al., 2025b).

Assessing Skin on a Range of Skin Tones

The nurse assesses skin from head to toe at admission and regularly after that, with a focused check of high-risk areas at each contact (Forest-Lalande et al., 2025; Norton et al., 2025). Assessment must work on every skin tone. Methods that depend on spotting redness miss problems on darker skin; Wounds Canada notes that judging by sight alone is a challenge on darkly pigmented skin and is often wrong (Norton et al., 2025). The nurse uses sight, touch and the person's own description together.

- **Lighting:** natural, halogen or indirect light shows colour best; fluorescent light casts a bluish tint that can hide changes (Black & Simende, 2020; Pusey-Reid et al., 2023).
- **Baseline skin tone:** at the first assessment, the nurse records the person's usual skin tone in descriptive words or with a colour chart, not with an ethnic or racial label (Black & Simende, 2020; Norton et al., 2025).
- **Colour:** on darkly pigmented skin, redness may not be visible; it may show instead as a patch darker than the person's usual skin, and changes in pigment are more useful than redness (Black & Simende, 2020; Forest-Lalande et al., 2025). Wet, macerated skin can look grey-white and wrinkled on darker skin (Forest-Lalande et al., 2025). The nurse compares a suspicious area with the same area on the other side of the body or with nearby healthy skin (Pusey-Reid et al., 2023).
- **Touch:** the nurse feels for warmth or coolness, moisture, texture, swelling, and firmness or bogginess compared with nearby skin. Bruising, **induration** (hardening), bogginess and changes in turgor can signal deep damage even when the skin is intact (Orsted et al., 2025a). Palpation is especially important on darker skin, where differences in temperature, consistency and pain guide the assessment (Norton et al., 2025).
- **The person's own words:** the nurse asks whether any area is sore, itchy, burning or different from usual.

- **Turgor:** pinched skin should spring back quickly. Because ageing skin loses elastin, slow recoil is harder to interpret in older adults, so turgor is never used alone to judge hydration (Chapter 3).

The nurse describes any lesion in plain terms: where it is, its size in millimetres or centimetres, its shape and colour compared with the person's usual skin, whether it is raised or flat and dry or weeping, and whether it is new. Warning signs of skin cancer are in section 35.6.

Documentation uses words and measurements, not only labels (Chapter 1). Some services add serial digital photographs to follow a wound over time (Orsted et al., 2025a). Photographs are taken only where employer policy allows, with the person's consent and with privacy protected (Chapter 1).

Moisture and Fragile Skin

Moisture-associated skin damage (MASD) is inflammation and erosion of skin caused by long contact with urine, stool, sweat, wound drainage or stoma output (Forest-Lalande et al., 2025). Wet skin swells, its barrier weakens, its pH rises, and friction and shear damage it more easily. Wounds Canada describes four types:

- **Incontinence-associated dermatitis (IAD):** irritation from urine, stool or both, usually on the perineum, buttocks and upper inner thighs, with inflammation and pain as the main features. Bacteria convert urea in urine to ammonia, which raises skin pH and weakens the skin's protective acid layer.
- **Intertriginous dermatitis:** damage from sweat and friction in skin folds, such as under the breasts or in the groin, often complicated by yeast (*Candida*).
- **Periwound MASD:** damage from drainage to the skin within a few centimetres of a wound.
- **Peristomal MASD:** damage around a stoma (Chapter 25).

Care follows three steps: cleanse gently with a pH-balanced, soap-free cleanser and pat dry; protect with a barrier such as a film-forming spray or a petrolatum, zinc oxide or dimethicone product; and restore the barrier with a moisturizer (Forest-Lalande et al., 2025). Controlling the source of moisture matters most; continence care is in Chapter 28.

A **skin tear** is a wound from trauma caused by mechanical force, such as handling during care or pulling off an adhesive; its depth varies, but it does not go through the subcutaneous layer (Nokaneng et al., 2025). People who need help with daily activities are at higher risk. The International Skin Tear Advisory Panel (ISTAP) classifies tears by the skin flap: Type 1, no skin loss (a linear tear, or a flap that can be laid back over the wound bed); Type 2, partial flap loss (the flap cannot cover the whole bed); and Type 3, total flap loss with the whole wound bed exposed. Moisturizing twice a day has been shown to cut the number of skin tears by half. Gentle handling with glide sheets rather than fingertip grips, long sleeves or shin guards, and silicone tape also help. When a tear happens, the nurse applies gentle pressure, cleanses, eases a living flap back into place and covers it with a silicone dressing marked with an arrow showing which way to remove it. Adhesive closure strips are no longer preferred, and films or hydrocolloids with acrylic or rubber adhesives and iodine-based products are not recommended (Nokaneng et al., 2025).

LIFESPAN CONSIDERATIONS

Skin in Older Adults

- **Thinner, drier skin:** ageing skin tears, bruises and breaks down more easily and heals more slowly (Orsted et al., 2025b). Bathing with warm rather than hot water, using soap-free cleansers and moisturizing twice a day protect it (Nokaneng et al., 2025).
- **Reduced sensation:** an older adult may not feel pressure building on a heel or under a device. The nurse checks these areas rather than waiting for a complaint (Orsted et al., 2025b).
- **Cognitive impairment:** a person with dementia or delirium may not report pain from a pressure area or skin tear. Restlessness, guarding or resisting care can be the first sign (Chapter 8).
- **Medicines:** anticoagulants, antiplatelet drugs, systemic corticosteroids and immunosuppressants can increase bruising or slow healing (BC Provincial Nursing Skin and Wound Committee, 2011; Orsted et al., 2025b). The nurse notes them in the skin assessment.
- **Help with daily activities:** people who need assistance are at higher risk of skin tears, so safe handling matters at every transfer (Nokaneng et al., 2025).

- **Younger adults:** pressure injury is not only a problem of age. Adults of any age with reduced mobility or sensation, such as after spinal cord injury (Chapter 32), are at high risk (Norton et al., 2025).

35.2 Pressure Injuries

How Pressure Injuries Develop

A **pressure injury** is localized damage to the skin and underlying soft tissue, usually over a bony prominence or under a medical or other device. It results from pressure, or pressure combined with shear (Edsberg et al., 2016; Norton et al., 2025). Pressure squeezes small blood vessels between bone and the surface beneath, so tissue is starved of oxygen. Pressure is greatest deep down: next to a bony prominence it can reach three to five times the pressure at the skin surface. Damage can therefore start in muscle and show on the skin later. A pressure injury can begin in as little as two hours, and emergency departments are one setting where this happens (Norton et al., 2025).

Shear is the force created when the skeleton slides one way while the skin is held in place by the surface, as when a person slides down in bed with the head raised. Shear distorts deeper tissue and roughly doubles the harm of pressure. Friction does not cause pressure injuries by itself, but it grips the skin so that shear can occur (Norton et al., 2025). Conditions at the skin where it meets a mattress or chair, sometimes called the **microclimate**, also matter, especially moisture. Moisture weakens the skin and increases friction between skin and sheets, so sweat, incontinence and wound drainage add to the risk (Forest-Lalande et al., 2025; Norton et al., 2025).

Risk comes from both the person and the environment. Wounds Canada lists reduced mobility, sensory loss, incontinence, malnutrition and dehydration, anemia, a previous pressure injury, vascular disease, a reduced level of consciousness, hypoxia, pain, serious chronic illness or the end of life, extremes of age, sedating medicines, polypharmacy and restraint use (Norton et al., 2025).

A **device-related pressure injury** forms under or around a medical device, such as oxygen tubing, a splint or tracheostomy equipment, and usually takes the shape of the device. It is staged with the same system as other pressure injuries. A **mucosal membrane pressure injury** forms on a moist lining, such as the lips or the inside of the nose, where a device has been in use; because of the tissue's structure it cannot be staged (Edsberg et al., 2016; National Pressure Injury Advisory Panel [NPIAP], n.d.).

Pressure injuries remain a problem in Canadian care. A Canadian analysis published in 2004, which pooled prevalence data gathered from 1990 to 2003, estimated an overall pressure ulcer prevalence of 26% across health-care settings, ranging from about 15% in community care to about 30% in non-acute care (Woodbury & Houghton, 2004). Wounds Canada, citing that study, reports that about 70% of these wounds were considered preventable and that pressure injury incidence in Canada has not decreased significantly (Norton et al., 2025). The Canadian Institute for Health Information (CIHI) tracks two indicators for long-term care residents: the percentage with a newly occurring stage 2 to 4 pressure ulcer, and the percentage with a stage 2 to 4 pressure ulcer that has become worse. Both come from standardized interRAI resident assessments and are adjusted for resident characteristics (CIHI, n.d.-a, n.d.-b). Wounds Canada notes higher rates of severe pressure injuries in people with darkly pigmented skin (Norton et al., 2025), and these higher rates are partly due to difficulty detecting injuries at earlier stages (Black & Simende, 2020). Early signs are harder to see on darker skin, so assessment that relies on redness delays detection. Using methods that work on every skin tone is part of equitable care (Chapter 2).

Prevention

Prevention starts at the first contact and continues for as long as the person is at risk.

- **Risk assessment:** Wounds Canada recommends screening when a person enters any care setting and again as risk, acuity or condition changes (Norton et al., 2025). Validated tools include the Braden Scale, the Norton Scale and the Waterlow Score. The employer chooses the tool for the setting, and no score replaces clinical judgment: a person with a "low-risk" score who cannot move after sedation is still at risk.
- **Skin checks:** the nurse inspects and palpates bony areas such as the sacrum, coccyx, heels, hips, elbows and back of the head, and skin under and around every device, whenever the person is repositioned and as policy requires (Norton et al., 2025).

- **Repositioning:** each person needs a written schedule matched to their condition. Wounds Canada gives the example of repositioning every 2 to 4 hours in bed and shifting weight every 15 minutes when sitting. Lift sheets and wedges reduce friction and shear, and keeping the head of the bed below about 30 to 35 degrees, unless the person's condition requires it to be higher, limits sliding (Norton et al., 2025).
- **Heels:** heels carry high pressure over a small area. **Offloading** means removing pressure from an area completely. Heels are managed separately from the mattress and floated off the bed; a wedge-shaped cushion or device that suspends the heels works better than a standard pillow, and the Achilles tendon is protected too (Norton et al., 2025).
- **Support surfaces:** a **support surface** is a mattress, overlay or cushion designed to redistribute pressure. It reduces pressure but does not replace repositioning. A person at risk who sits needs a pressure-redistributing cushion, and a person who uses a wheelchair needs a seating assessment by a skilled clinician such as an occupational therapist (Norton et al., 2025).
- **Prophylactic dressings:** some programs place multilayer silicone foam dressings over the sacrum or heels of people at risk to reduce friction and shear (Norton et al., 2025). The skin under them is still checked.
- **Moisture:** prompt cleansing and skin protection after incontinence or sweating, as described in section 35.1, and an individualized bowel and bladder plan (Chapter 28).
- **Nutrition and hydration:** screening with a validated tool and a dietitian referral when intake is poor (Norton et al., 2025); see section 24.1.
- **Mobility and teaching:** the nurse encourages safe movement, involves physiotherapy and occupational therapy, and teaches the person and family why position changes matter and how to check skin.

Staging and Care

Wounds Canada recommends classifying pressure injuries with the revised staging system of the National Pressure Injury Advisory Panel (NPIAP), which grades injuries by the deepest tissue damaged (Edsberg et al., 2016; Norton et al., 2025). Wounds Canada uses the paired term "category/stage"; this chapter uses "stage", as NPIAP does. Only pressure injuries are staged with this system; skin tears and burns have their own classifications, and MASD is not staged (Edsberg et al., 2016). Table 35.1 summarizes the stages. Three rules guide staging: (Figure 35.2)

- **No reverse staging:** the stage describes the deepest damage when the injury was first assessed. A stage 3 injury that fills with new tissue is documented as a healing stage 3, never as a stage 2 (Norton et al., 2025).
- **Unstageable pressure injury:** the base is hidden by **slough** (soft yellow, tan or grey dead tissue) or **eschar** (dry, dark, leathery dead tissue), so depth cannot be judged. Once the covering is removed, the injury will prove to be stage 3 or 4. Stable eschar on a heel or a limb with poor blood flow, meaning dry, attached and intact with no redness or softness around it, is not softened or removed (NPIAP, n.d.).
- **Deep tissue pressure injury (DTPI):** damage that starts at the bone–muscle interface and shows as persistent, non-blanching discolouration of intact or broken skin, or a blood-filled blister. Changes in pain and temperature often appear before any colour change. It may resolve or may open quickly to reveal deeper damage (NPIAP, n.d.). On darkly pigmented skin, a DTPI does not always look purple or maroon; in one study of African American patients, most DTPIs looked purple, but others looked grey, black, brown, blue or maroon (Black & Simende, 2020). The nurse therefore also relies on touch and on the person's report of pain.

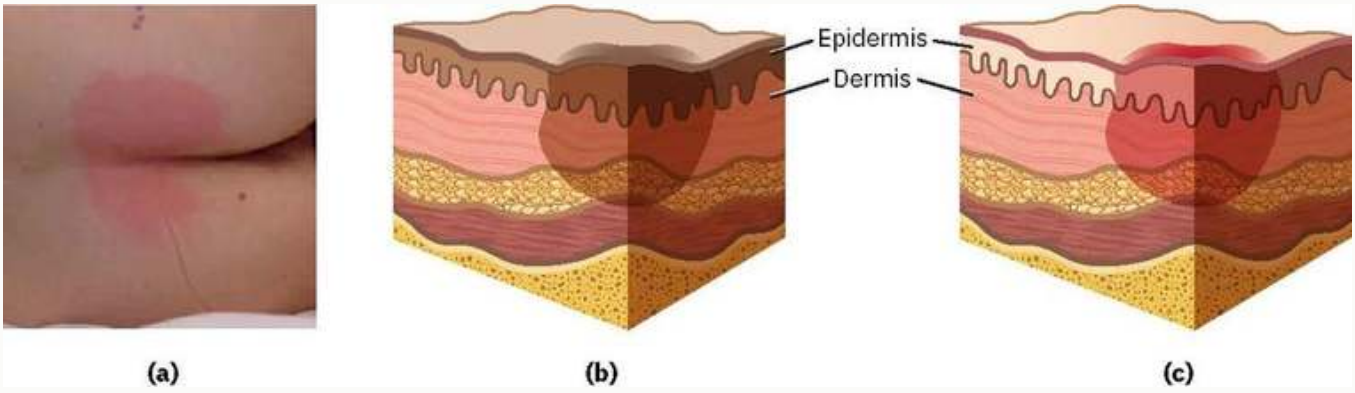

Figure 35.2 Stage 1 pressure injury: intact skin with localized, non-blanchable erythema, illustrated in clinical photograph (a) and comparative cross-sections of light skin (b) and dark skin (c). (credit: "Figure 28.5, Stage 1 Pressure Injury" by OpenStax, Medical-Surgical Nursing, CC BY 4.0 / CC BY-NC-SA 4.0)

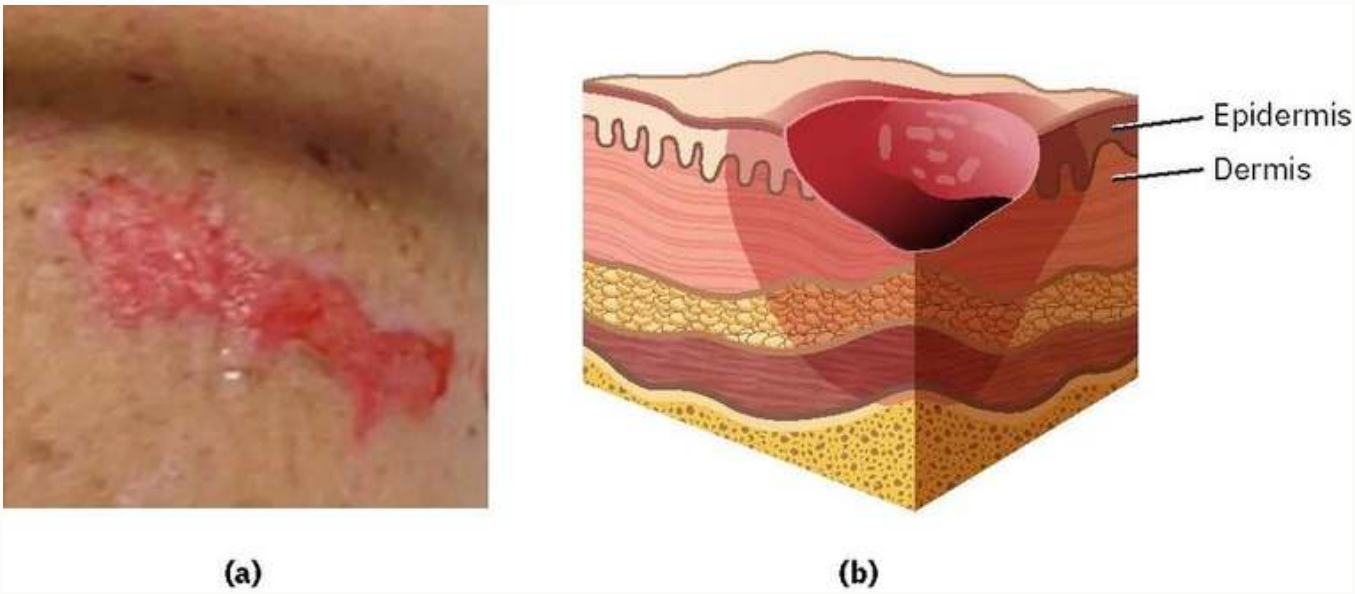

Figure 35.3 Stage 2 pressure injury: partial-thickness skin loss with exposed dermis, showing a viable, pink/red, moist wound bed without slough or granulation tissue. (credit: "Figure 28.6, Stage 2 Pressure Injury" by OpenStax, Medical-Surgical Nursing, CC BY 4.0 / CC BY-NC-SA 4.0)

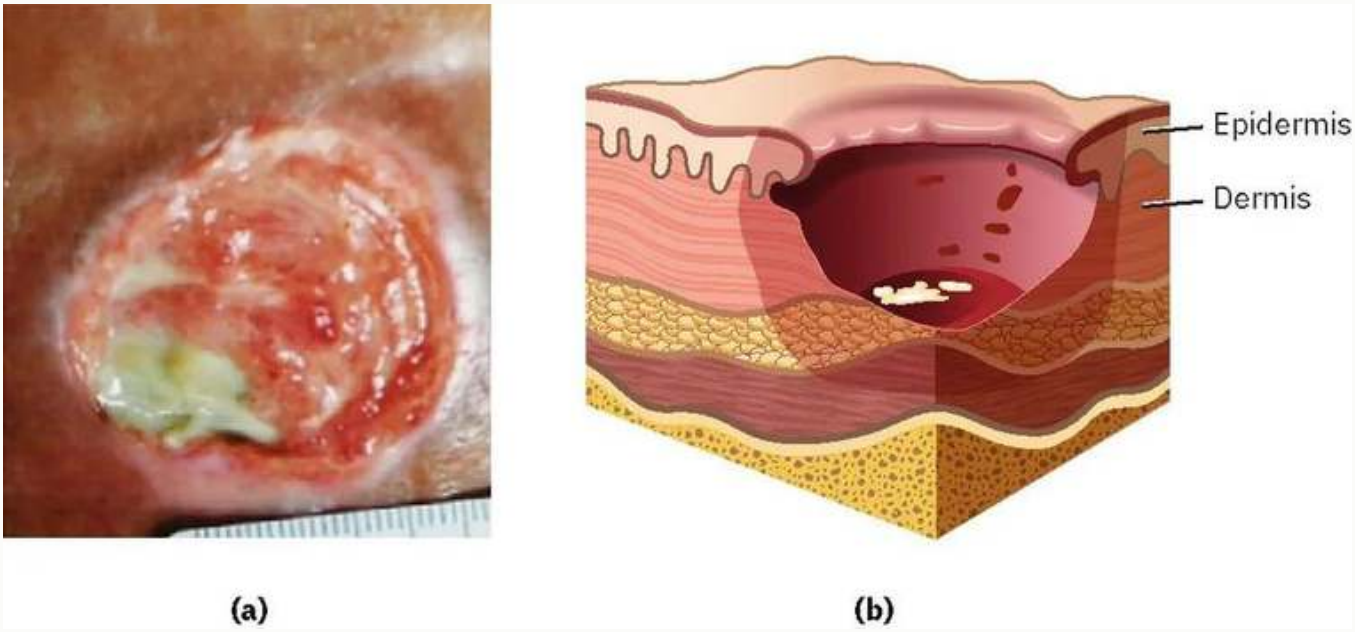

Figure 35.4 Stage 3 pressure injury: full-thickness skin loss with visible subcutaneous fat in the ulcer crater; bone, tendon and muscle are not exposed. (credit: "Figure 28.7, Stage 3 Pressure Injury" by OpenStax, Medical-Surgical Nursing, CC BY 4.0 / CC BY-NC-SA 4.0)

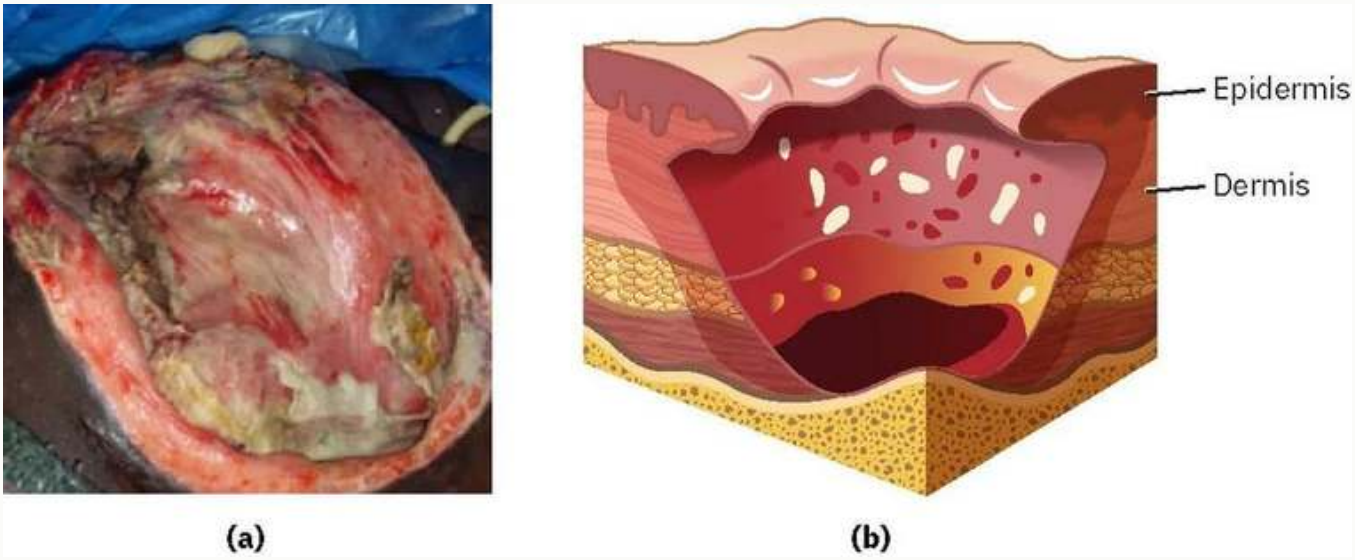

Figure 35.5 Stage 4 pressure injury: full-thickness skin and tissue loss with directly exposed and palpable fascia, muscle, tendon or bone. (credit: "Figure 28.8, Stage 4 Pressure Injury" by OpenStax, Medical-Surgical Nursing, CC BY 4.0 / CC BY-NC-SA 4.0)

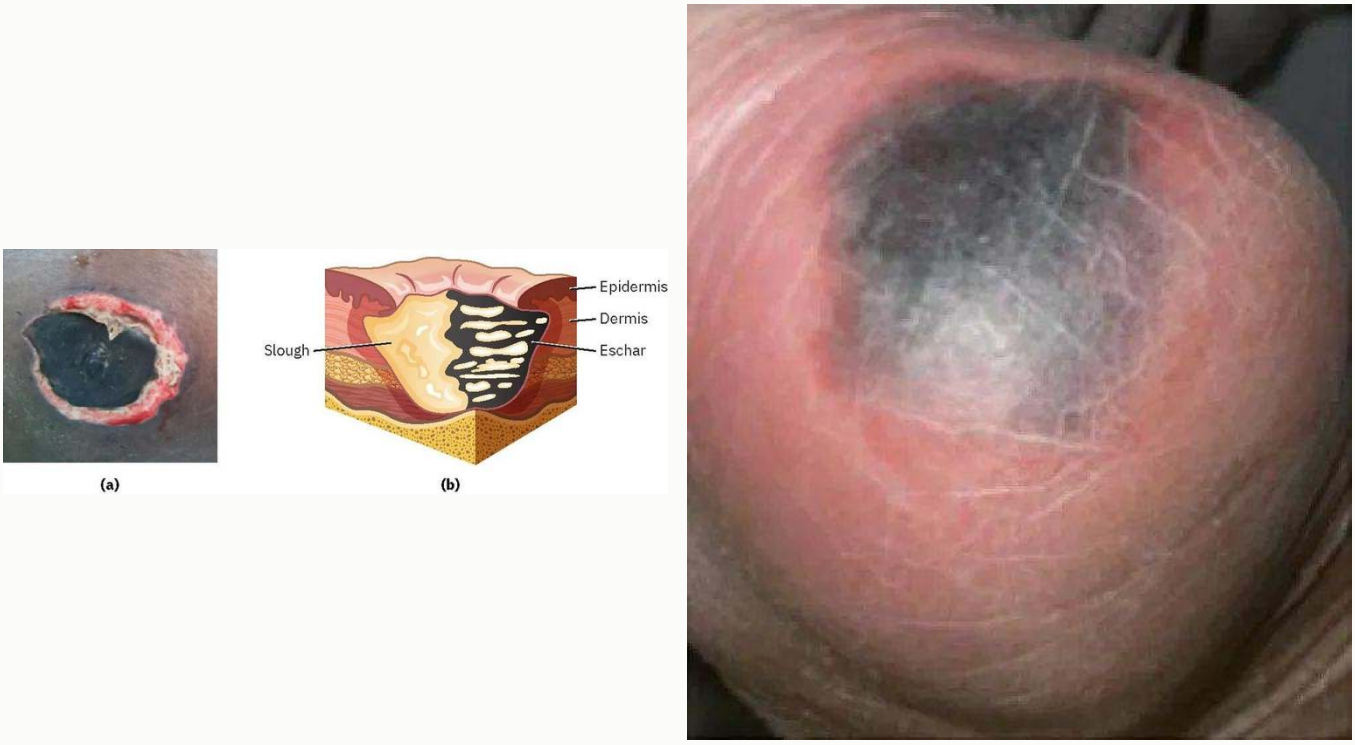

Figure 35.6 (a) Unstageable pressure injury with the true depth of tissue damage obscured by slough and eschar, alongside (b) a deep tissue pressure injury (DTPI) on a heel presenting as persistent, non-blanchable deep red/purple discoloration. (credit: panel [a] from "Figure 28.9, Unstageable Pressure Injury" and panel [b] from "Figure 28.10, Deep Tissue Pressure Injury" by OpenStax, Medical-Surgical Nursing, CC BY 4.0 / CC BY-NC-SA 4.0)

Care at every stage starts with removing the cause. The nurse keeps all pressure off the injury, floats injured heels, and addresses shear, moisture and nutrition; goals are set with the person and family (Norton et al., 2025). Local wound care then follows the wound bed preparation approach in section 35.3. Stage 3, stage 4 and unstageable injuries, and any injury that is not improving, are referred to the wound care team, which may include a Nurse Specialized in Wound, Ostomy and Continence (NSWOC), a dietitian and an occupational therapist. Surgical closure may be an option for some stage 3 and 4 injuries if it fits the person's goals (Norton et al., 2025). A wound that is not 20% to 40% smaller by week 4 is unlikely to heal by week 12 and is reassessed (Norton et al., 2025; Sibbald et al., 2022).

Documentation records the location, stage, size, wound bed, drainage, edges, surrounding skin, pain, the person's baseline skin tone, the prevention plan and who was notified, and whether the injury was present on admission (Norton et al., 2025; Chapter 1).

Table 35.1 Pressure injury stages (based on Edsberg et al., 2016; NPIAP, n.d.; Norton et al., 2025; Black & Simende, 2020)

Stage	What the nurse sees and feels	On darker skin tones	Care focus
Stage 1	Intact skin with a local area of colour change that does not blanch; the area may feel warmer, cooler, firmer or softer than nearby skin, and may be painful	Redness may not show; look for a patch darker than the person's usual skin and rely on temperature, firmness and pain compared with the other side	Offload completely, protect the skin, manage moisture, reassess often as policy requires
Stage 2	Shallow, partial-thickness loss of skin with exposed dermis; moist pink or red base, or an intact or broken fluid-filled blister; no fat, slough or eschar	Judge depth and the wound base as for any skin; redness in the surrounding skin may not show, so compare warmth and firmness with nearby skin	Offload, keep the wound moist and protected, control incontinence and moisture so the wound is not mistaken for or worsened by MASD

Stage	What the nurse sees and feels	On darker skin tones	Care focus
Stage 3	Full-thickness skin loss with fat visible; slough or eschar may be present; undermining and tunnelling may occur; no bone, tendon or muscle exposed	Depth is judged the same way; check the surrounding skin for warmth, firmness and colour change against baseline	Offload, follow wound bed preparation, manage drainage and dead space, refer to the wound care team
Stage 4	Full-thickness loss of skin and tissue with bone, cartilage, tendon, ligament, muscle or fascia visible or felt; slough, eschar, rolled edges, undermining or tunnelling common	Assess as for stage 3; watch for signs of deep infection	Offload, refer to the wound care team, watch for bone infection, consider surgical options with the person
Unstageable	Full-thickness loss whose depth is hidden by slough or eschar	Surrounding colour change may be subtle; touch and pain guide assessment	Do not stage until the base is visible; leave stable dry heel eschar in place; refer
Deep tissue pressure injury	Persistent, non-blanching deep red, maroon or purple area, or a blood-filled blister, over intact or broken skin; pain and temperature change often come first	May not look purple or maroon; may look grey, brown, black or blue, or be found mainly as a painful, firm, boggy, warm or cool area	Offload completely, protect, monitor closely for rapid change, report and document

PRACTICE STORY

Feel the Heel

Names and details are fictional; this is a composite story.

Nurse: Ruth Asamoah, RPN. Years in practice: 6. Setting: medical unit, Ontario.

Mr. Winston Sterling was 74 and on day three of treatment for pneumonia. He was a retired transit mechanic, a Black man with deep brown skin, and he hated being in bed. His Braden score that morning put him at moderate risk, and the night nurse's note read "skin intact, no redness."

When I helped him turn after breakfast, I did what I always do: I took his socks off and held each heel in my hand. The left heel felt like the right one. The right heel did not. It was warmer, and there was a firm, slightly spongy area about the size of a loonie on the back of the heel. In the window light, the skin there looked a shade darker than the rest of his heel, almost plum. Under the ceiling lights, I would have walked past it.

"Does that hurt?" I asked. He said it had ached all night, "like a bruise," but he hadn't wanted to bother anyone.

I didn't know exactly what it was yet, but I knew it was new, and I knew pressure was the likely cause. I floated both heels with the heel-suspension cushion our unit stocks, checked that his Achilles tendons were free, and lowered the head of the bed as far as his breathing allowed. Then I found Lindiwe, the RN on our team, and told her what I had felt, seen and heard, and that I had offloaded the heel. She came and assessed it with me, and we sent a referral to our wound care nurse that morning. I charted the size, colour against his usual skin tone, warmth, firmness, his pain and the actions taken.

The wound care nurse saw him that afternoon and documented a suspected deep tissue pressure injury. Over the next week the area stayed closed. Mr. Sterling started calling me "the heel detective."

Reflect: What helped Ruth find this injury when an earlier check had not? Using authority, competence and context (section 1.3), which parts of this care were within Ruth's own practice, and when did she need to consult the RN?

35.3 Wound Healing and Wound Care

How Wounds Heal

Healing follows four overlapping phases (Orsted et al., 2025b):

- **Hemostasis:** within minutes, platelets plug damaged vessels, a clot forms and growth factors are released.
- **Inflammation:** for up to about four days, white blood cells clear debris and bacteria. Warmth, swelling, pain and colour change around a new wound are expected at this stage (Chapter 4).
- **Proliferation:** from about day 4 to about day 21 in an acute wound, fibroblasts lay down collagen and new capillaries grow, forming **granulation tissue**, the moist, bumpy new connective tissue that fills a wound from its base. The wound then contracts,

and new epithelial cells cover the surface. Healthy granulation forms a firm, level base; granulation that is bright red, fragile and bleeds easily can signal infection (Sibbald et al., 2022).

- **Remodelling:** collagen is reorganized for up to two years. A healed scar regains only about 70% to 80% of the strength of uninjured skin.

Wounds close in one of three ways (BC Provincial Nursing Skin and Wound Committee, 2011). In **primary intention**, the wound edges are brought together with sutures, staples or tape and heal without the need to fill with granulation tissue, as in most surgical incisions. In **secondary intention**, the wound is left open and fills with granulation tissue from the base up, as most pressure injuries do. In **delayed primary intention**, or delayed primary closure, a contaminated wound is left open for about 4 to 6 days and then closed. Surgical wounds are covered in section 35.4.

An acute wound moves through the phases in order once its cause is removed. A **chronic wound**, also called a wound of long duration, stalls, usually in the inflammatory phase, because something that blocks healing has not been corrected (Orsted et al., 2025b). Common barriers include:

- poor blood supply and oxygen (Chapter 19);
- high blood glucose (Chapter 22);
- poor intake of protein, energy and micronutrients such as iron, zinc and vitamins A and C (section 24.1);
- persistent bacteria and infection;
- smoking;
- pressure that is not offloaded;
- some medicines, including systemic corticosteroids, anticoagulants, antiplatelet drugs, immunosuppressants and cancer drugs (BC Provincial Nursing Skin and Wound Committee, 2011; Orsted et al., 2025a, 2025b).

Assessing a Wound

Wound bed preparation is a framework for wound care that starts with the whole person, not the dressing. Its first steps are to identify and treat the cause, address the person's concerns such as pain and quality of life, and decide whether the wound can heal (Sibbald et al., 2022). A wound is:

- **healable** when its cause can be corrected and its blood supply is adequate;
- **maintenance**, or non-healing, when the blood supply is adequate but the person cannot follow the plan or lacks the resources to do so;
- **non-healable** when the blood supply is inadequate or the cause cannot be corrected.

This decision sets the goal: closure for a healable wound, and stability, comfort and infection control for the others (Orsted et al., 2025a; Sibbald et al., 2022).

The nurse then assesses the wound itself, the same way each time, using the employer's assessment form (Orsted et al., 2025a):

- **Location:** marked on a body map, with several wounds numbered.
- **Size:** length, width and depth in centimetres, measured with the same method and position at each assessment so that change is real.
- **Undermining and tunnelling: undermining** is tissue destroyed under intact skin at the wound edge, forming a shelf; **tunnelling** is a narrow channel from the wound into deeper tissue. Both are measured and their direction recorded.
- **Wound bed:** the type of tissue present (granulation, slough, eschar or new epithelium), often as approximate percentages.
- **Exudate: exudate** is fluid that drains from a wound; the nurse records its amount, type and colour.
- **Edges and surrounding skin:** whether the edges are attached or rolled; and maceration, induration, edema, warmth and colour change compared with the person's baseline.
- **Pain and odour:** pain at rest and during dressing changes, and odour after cleansing. Pain that is new or increasing can signal infection or deterioration (Orsted et al., 2025a).

A wound that is shrinking by 20% to 40% by week 4 is on track; one that is not is reassessed with the team (Sibbald et al., 2022).

Cleansing and Dressings

Cleansing removes debris and loose bacteria with as little harm to new tissue as possible. Options include sterile normal saline, sterile water and potable (drinkable) tap water, at body temperature. Irrigation at 4 to 15 pounds per square inch (psi), roughly 28 to 103 kPa, is effective and generally safe, while scrubbing with gauze is discouraged. When infection is suspected, a cleanser with an antiseptic, such as polyhexamethylene biguanide (PHMB), a hypochlorous acid solution or povidone-iodine, may be used, short term and with caution, because antiseptics can also damage healthy cells (Orsted et al., 2025a). The surrounding skin is also cleansed well and patted dry (Forest-Lalande et al., 2025). The order and employer policy set the solution.

No single dressing suits every wound. The choice depends on the goal (healable, maintenance or non-healable), the phase of healing, the amount of drainage, signs of infection, and the person's comfort, lifestyle, skills and costs (Orsted et al., 2025a). In a healable wound the aim is **moisture balance**: enough moisture for cells to move across the wound bed, but not so much that the edges macerate. A dry wound needs a dressing that adds moisture, and a wet wound needs one that absorbs (Orsted et al., 2025a; Sibbald et al., 2022). Table 35.2 matches dressing categories to wound needs.

Maintenance and non-healable wounds are handled differently. Because moisture can encourage bacterial overgrowth in a wound that cannot heal, the aim is to reduce moisture and bacteria with low-toxicity antiseptics such as povidone-iodine, chlorhexidine or PHMB, and to remove only loose slough conservatively (Sibbald et al., 2022). Dry, stable eschar on a heel or a limb with poor blood flow is kept dry and left in place (Norton et al., 2025; NPIAP, n.d.).

At a dressing change, the nurse follows the employer's hand hygiene and technique (Chapter 4), offers analgesia beforehand when changes are painful, and removes dressings gently (Chapter 5). Dressing choice itself is a key to pain control at removal and application (Orsted et al., 2025a). The nurse protects the surrounding skin, labels and documents the change, and gives a product a fair trial before switching (Orsted et al., 2025a). Cleansing, irrigating or packing a wound below the dermis is a controlled act. In Ontario, RNs and RPNs may perform it with an order, or initiate it without one where the setting allows; nurses in public hospitals cannot initiate controlled acts. The nurse also needs the competence, and employer policy sets the context (College of Nurses of Ontario [CNO], 2025; section 1.3).

Table 35.2 Matching the dressing to the wound (based on Orsted et al., 2025a; Sibbald et al., 2022; Nokaneng et al., 2025; Norton et al., 2025)

Wound need	Dressing category	Examples of when used	Nursing points
Add moisture	Hydrogels	Dry wound bed in a healable wound; helps soften dry slough	Protect surrounding skin from maceration; not used for MASD; not for stable heel eschar or a non-healable wound
Keep moisture in and protect	Films, hydrocolloids, contact layers	Shallow wounds with little drainage	Avoid films and hydrocolloids with acrylic or rubber adhesives on skin tears or skin at high risk of tearing; check edges for rolling or lifting
Absorb drainage	Foams, alginates, gelling fibres, superabsorbents	Moderate to heavy drainage; fibres can loosely fill dead space	Change before the dressing leaks; never pack tightly; record the amount and type of drainage
Reduce bacteria	Antimicrobial dressings and antiseptics (silver, iodine products such as povidone-iodine, PHMB, chlorhexidine)	Local infection in a healable wound; ongoing bacterial control in maintenance and non-healable wounds	Use for a set trial and reassess; iodine is not used on skin tears; report signs of spreading infection rather than relying on a dressing
Protect fragile skin and prevent injury	Silicone contact layers and silicone foams	Skin tears; prophylaxis over the sacrum or heels in people at risk	Mark the direction of removal on skin tear dressings; lift the dressing to check the skin underneath as policy requires

Wound need	Dressing category	Examples of when used	Nursing points
Reduce moisture in a non-healable wound	Antiseptic tulle, povidone-iodine, PHMB gauze	Wounds with inadequate blood supply or a cause that cannot be corrected	Goal is a dry, stable, comfortable wound; leave stable dry eschar in place

Wound Infection

All open wounds contain bacteria. Wounds Canada describes a continuum from contamination and colonization to local infection, spreading infection and systemic infection (Orsted et al., 2025a):

- **Local infection** is confined to the wound. Its signs may be subtle, especially in wounds of long duration: delayed healing, more drainage, granulation that is bright red and bleeds easily, and bridges of tissue across the wound. Classic signs are redness, warmth, swelling, pus, wound breakdown, new or increasing pain and increasing odour; redness can be hard to see on darker skin or with edema (Orsted et al., 2025a; Sibbald et al., 2022).
- **Spreading infection** extends beyond the wound: inflammation more than 2 cm from the edge, spreading hardness, or streaks along lymph vessels (lymphangitis). Cellulitis is covered in section 35.4.
- **Systemic infection** adds malaise, loss of appetite and fever, and can progress to sepsis (Chapter 4).

Infection is diagnosed mainly from these clinical signs. The nurse reports new or increasing pain, a wound that deteriorates or stops improving, and any sign of spreading infection promptly, using SBAR (Chapter 6). Signs of systemic infection or sepsis call for immediate escalation (Chapter 4). When the team needs laboratory confirmation, a wound swab is collected as ordered. Wounds Canada prefers the Levine technique: the nurse cleanses the wound first, moistens the swab with sterile saline if the wound is dry, then presses the swab firmly into the cleanest viable tissue and rotates it, avoiding pus, slough and dead tissue (Orsted et al., 2025a).

GOING DEEPER

Biofilm, Infection and the Wound Swab

Required for RN students; optional for PN students.

Biofilm is a complex community of bacteria and fungi held together in a thick, slimy coating made of sugars and proteins. Wounds Canada reports biofilm in roughly 60% to 90% of wounds of long duration, where it delays healing (Orsted et al., 2025a). A standard wound culture cannot detect biofilm. Clues include a wound that fails to respond to appropriate antibiotics, delayed healing that returns once antibiotics stop, fragile overgrown granulation, increased drainage and low-grade inflammation.

The wound bed preparation authors offer two memory aids for separating surface from deeper infection (Sibbald et al., 2022). **NERDS** signals local infection: Nonhealing, Exudate increase, Red friable granulation, Debris, Smell. **STONEES** signals deeper or surrounding infection: Size increase, Temperature increase, Os (probing to bone), New areas of breakdown, Exudate increase, Erythema or Edema, Smell. Three or more NERDS signs suggest topical antimicrobial treatment; three or more STONEES signs suggest the prescriber should consider systemic antibiotics. Because colour change can be hard to see on darker skin or with edema, warmth is checked against the matching skin on the other side.

Wounds Canada directs that a swab is not taken from pus, slough or dead tissue; the Levine technique samples the cleanest area after the wound is cleansed (Orsted et al., 2025a). The swab label includes the site, time, collector and relevant history, such as current antibiotics or diabetes.

PATIENT EDUCATION

Caring for a Wound at Home

- **Clean hands first:** wash your hands before and after touching your wound or dressing. Keep dressing supplies clean and dry.
- **Follow your dressing plan:** change the dressing as your nurse showed you. Ask before showering or soaking the wound.
- **Take pressure off:** if your wound is on a heel, hip or tailbone, keep weight off it and change position often.
- **Eat and drink well:** protein, fruit, vegetables and fluids help skin repair (section 24.1). If you have diabetes, keeping your blood sugar in your target range helps your wound heal (Chapter 22).
- **Stop smoking if you can:** smoking slows healing. Ask your team about help to quit.
- **Manage pain:** take pain medicine as advised before dressing changes if they hurt, and tell your nurse if pain is getting worse.

- **Call your nurse or health-care provider if:** the wound is more painful, warm or swollen; there is pus, a bad smell or more drainage; a change in colour is spreading around the wound; the wound is getting bigger; or you feel feverish or unwell.
- **Call 9-1-1 if:** you feel very unwell, confused, short of breath or faint.
- **Keep follow-up visits,** even if the wound looks better.

35.4 Surgical Wounds and Skin Infections

A surgical incision is a planned wound, yet it can still become infected, open or heal slowly, and a small crack in the skin can let in a spreading infection. This section covers incision care, complications that need fast action and common skin infections. Infection control, antimicrobial resistance and sepsis are taught in Chapter 4, and perioperative care in Chapter 7.

Surgical Wounds

Most incisions are closed with sutures, staples, skin glue or adhesive strips and heal by primary intention (section 35.3). Wounds Canada's 2025 recommendations give the nurse a timeline to check against. The edges should be sealed by new epithelium along the whole incision by about day 4. Between days 5 and 9, the nurse should be able to feel a **healing ridge**, a firm band of new collagen under the full length of the incision. A missing ridge, or any drainage after day 9, is not expected and is reported (Tecson et al., 2025). A complete assessment looks at the incision line and the skin around it (Figure 35.7).

Figure 35.7 A surgical incision closed with metal staples seven days after surgery, healing by primary intention with well-approximated edges. (credit: “Surgical staples2” by Llywrch/Wikimedia Commons, CC BY-SA 2.5)

In the first days, mild swelling, warmth and tenderness are part of normal inflammation. Colour change is easy to see on lighter skin but may be hard to see on darker skin, so the nurse feels for warmth and firmness, compares the area with nearby skin and asks the person what feels different (Wounds International, 2023). A closed incision usually needs only a dry, sterile cover dressing for the first 24 to 48 hours. Most patients may shower after 48 hours, but the surgeon decides. Sutures and staples usually stay in for 7 to 10 days and are removed sometime between days 9 and 14, later if healing is slow (Tecson et al., 2025).

A **surgical site infection (SSI)** is an infection of the incision or of the deeper tissues or organ space after an operation. Wounds Canada notes that superficial SSIs are watched for 30 days after surgery, deeper SSIs for 30 to 90 days depending on the operation, and infections around implants such as a hip or knee replacement for up to a year (Tecson et al., 2025). Signs include pain or tenderness that is new or increasing (pain or tenderness by itself can signal infection), spreading swelling and warmth, cloudy or foul-smelling drainage, fever and breakdown of the incision (British Columbia Provincial Nursing Skin and Wound Committee, 2011; Tecson et al., 2025). Confirming infection and recognizing sepsis are covered in Chapter 4.

Dehiscence is a partial or complete separation of the edges of a closed incision. It can expose the tissue beneath or allow organs to push through. Wounds Canada describes it as most likely between days 5 and 8, often around day 7 (Tecson et al., 2025), and an international consensus places most cases between days 4 and 14 (World Union of Wound Healing Societies [WUWHS], 2018). Risk factors include obesity, diabetes, smoking, emergency surgery, age over 65, a long operation, low body temperature during surgery and wound infection (WUWHS, 2018). Coughing, abdominal distension and ileus raise the pressure on an abdominal incision (Downey, 2020). Warning signs are a sudden rise in pain, new pink, watery (serosanguineous) drainage, swelling or a fluid collection under the incision, and no healing ridge by days 5 to 9. Patients sometimes say they felt something "give way" when they coughed

Figure 35.8 Dehiscence of an inguinal hernia repair incision, with separated wound edges and a red granulation bed healing by secondary intention. (credit: "Wound Dehiscence post inguinal hernia repair 2014-05-27 00-46" by Phoenix119/Wikimedia Commons, CC BY-SA 3.0)

(Downey, 2020; WUWHS, 2018). Even a small opening is reported, and a separated incision is never irrigated before the nurse has spoken with the surgeon (Tecson et al., 2025; Figure 35.8).

Evisceration is the protrusion of organs, such as bowel, through a separated abdominal incision. It is a surgical emergency (Tecson et al., 2025). A Canadian provincial guideline directs the nurse to stay with the patient and have the physician or nurse practitioner (NP) called at once (9-1-1 outside hospital), cover any exposed tissue with a dressing wet with warm sterile normal saline, place the patient in a low Fowler's position (20 degrees or less) with the knees bent, never try to push the organs back, and watch vital signs for shock until help arrives (British Columbia Provincial Nursing Skin and Wound Committee, 2011). Oral intake is withheld in case surgery is needed (Downey, 2020). The nurse calls the rapid response team if signs of shock appear (Chapter 6; Table 35.3).

Table 35.3 Surgical wound problems and first actions (British Columbia Provincial Nursing Skin and Wound Committee, 2011; Downey, 2020; Tecson et al., 2025; WUWHS, 2018)

Problem	What the nurse sees	First actions	Who to tell
Healing slower than expected	No healing ridge by days 5 to 9; drainage still present after day 9; edges not fully sealed	Measure and describe the incision; check nutrition, glucose and other factors that slow healing (section 35.3)	Surgeon or most responsible provider; wound care nurse if the employer has one
Possible surgical site infection	New or increasing pain; spreading warmth and swelling; colour change (red on lighter skin; on darker skin, a patch darker than the usual skin or no visible change); cloudy or foul-smelling drainage; fever	Assess vital signs and the whole incision; document drainage; follow the infection prevention steps in Chapter 4	Surgeon promptly; rapid response team if signs of sepsis
Dehiscence	Edges pulling apart; sudden pink, watery drainage; patient felt something give way	Cover with sterile gauze moistened with sterile normal saline; low Fowler's position, knees bent; do not irrigate before speaking with the surgeon; check vital signs	Surgeon at once
Evisceration	Bowel or other organs visible through the opened incision	Stay with the patient and call for help; cover with a dressing wet with warm sterile normal saline; do not push organs back; low Fowler's position, knees bent; nothing by mouth; watch for shock	Surgeon or NP at once; rapid response team if unstable

Negative pressure wound therapy (NPWT) uses a sealed dressing connected by tubing to a pump that applies suction to a wound. It is widely used for open wounds, including dehisced wounds that are deep or produce a lot of exudate, and Wounds Canada advises considering it as a first-line treatment for a dehisced breastbone (sternal) wound after cardiac surgery (Tecson et al., 2025; WUWHS, 2018). A special dressing may also be placed over a closed incision in the operating room for patients at high risk of complications and left in place for 5 to 7 days. NPWT is not placed directly over exposed organs, blood vessels, nerves or bowel joins (anastomoses), and each device has its own warnings (WUWHS, 2018; Figure 35.9).

Cellulitis and Other Skin and Soft Tissue Infections

Cellulitis is a spreading infection of the skin and the tissue just beneath it. Most cases are caused by streptococci; *Staphylococcus aureus* is more likely when there is an open wound, a penetrating injury or injection drug use (Stevens et al., 2014). The affected area

is warm, swollen and tender, and a change in colour spreads outward. On lighter skin it looks red. On darker skin, redness may not be visible; the change may show as a patch darker than the person's usual skin or be hard to see, and the skin may feel tighter to the touch (Black & Simende, 2020; Wounds International, 2023). Some people also have fever, a fast heart rate or confusion (Stevens et al., 2014; Figure 35.10).

People who have had cellulitis often have it again. Edema, obesity, eczema, venous insufficiency and cracked, scaly or moist skin between the toes all raise the risk (Stevens et al., 2014). The diagnosis is usually clinical, and blood cultures are not routinely needed (Stevens et al., 2014).

The nurse assesses the whole limb and compares it with the other side. A UK consensus advises marking the edge of the affected area and writing the date beside it when possible (British Lymphology Society & Lymphoedema Support Network, 2016). Because colour may not show the edge on darker skin, the nurse also records the extent of warmth, swelling and tenderness. Elevating the limb and treating edema and toe-web problems are recommended (Stevens et al., 2014). A person with typical cellulitis and no signs of systemic illness usually receives an oral antibiotic active against streptococci, such as a penicillin or a first-generation cephalosporin (for example, cephalexin). Intravenous (IV) antibiotics, hospital care and, in some cases, coverage for methicillin-resistant *S. aureus* (MRSA) are considered when there are signs of systemic illness, a penetrating injury or injection drug use (Stevens et al., 2014; Chapter 4). Low blood pressure, new confusion or a rising heart rate are escalated as possible sepsis.

Figure 35.9 Negative pressure wound therapy applied over a midline abdominal surgical incision, with a sealed foam dressing and suction tubing kept separate from the adjacent colostomy pouch. (credit: "Colostomy with wound vacuum (negative-pressure wound therapy) applied" by Hu Nhu/Wikimedia Commons, CC BY 4.0)

Figure 35.10 Cellulitis of the toes and forefoot, with spreading redness and swelling of the skin.

An **abscess** is a walled-off collection of pus. Its main treatment is incision and drainage; antibiotics are added for people with systemic signs or weakened immune systems (Stevens et al., 2014).

A **necrotizing soft tissue infection (NSTI)** destroys the deeper tissues, such as the fat and the fascia around the muscles, and can be fatal. Invasive group A streptococcal disease, which causes about 35% to 40% of these infections, has been rising in Canada (Deb et al., 2024). At first it can look like ordinary cellulitis. Red flags are pain that seems out of proportion to what the nurse can see, rapid spread, hard, wooden-feeling tissue beyond the visible skin change, blisters (bullae), dusky or dead-looking skin, a crackling feel under the skin (crepitus), confusion and signs of shock (Deb et al., 2024; Stevens et al., 2014). Blisters and crepitus are late signs, so their absence does not rule out NSTI. Because death is directly related to the time to surgery, the nurse escalates at once; urgent surgical removal of dead tissue is the main treatment, and imaging should not delay it (Deb et al., 2024). Cases caused by group A streptococci are reported to public health.

CLINICAL JUDGMENT

Red and Spreading

Names and details are fictional; this is a composite story.

Raymond Tessier, 58, has type 2 diabetes and was admitted 18 hours ago with cellulitis of the right lower leg. He is receiving IV antibiotics. The edge of the affected area was marked and dated on admission.

- **Recognize cues:** At 0300, he rates his leg pain 10 out of 10, up from 4, and says the pain "goes all the way up." The skin above the marked edge feels hard and is darker and dusky in two places. His blood pressure is 88/50 mm Hg (usually 134/80), heart rate 124, and he is slow to answer questions.
- **Analyze cues:** Pain far worse than the skin findings, spread past the marked edge despite antibiotics, hard tissue and low blood pressure do not fit improving cellulitis. They fit a necrotizing soft tissue infection with septic shock.
- **Prioritize hypotheses:** Septic shock from a necrotizing infection is the most urgent problem; poor glucose control and pain matter but come after.
- **Generate solutions:** Get immediate help, support circulation as ordered and arrange an urgent surgical assessment.
- **Take action:** The nurse calls the rapid response team, stays with Mr. Tessier, gives the ordered IV fluid bolus, checks his capillary blood glucose and gives a situation, background, assessment, recommendation (SBAR) report (Chapter 6) that names the concern: "I am worried this is necrotizing fasciitis." The team calls the surgeon.
- **Evaluate outcomes:** The nurse rechecks blood pressure, heart rate, mental status and the leg every 15 minutes until he goes to the operating room, and documents the times of each finding and call.

Reflect: Which cue would you have found first, and why does the time of escalation matter so much in this infection?

35.5 Burns

A **burn** is damage to the skin or deeper tissues caused by heat, chemicals, electricity, radiation, friction or extreme cold. A small scald can be cared for at home, while a large burn affects every body system. This section covers how burns are classified, first aid and emergency care, and nursing care through recovery.

Types and Depth of Burns

Most burns come from heat: scalds from hot liquids, steam or grease, contact with hot objects, and flame or flash. Electrical burns come from current flowing through the body. Chemical burns depend on the agent, its strength and the contact time; alkalis can cause deeper damage than acids. Radiation burns include sunburn and skin reactions to radiation therapy (Wallace et al., 2025).

Wounds Canada's 2025 burn chapter, drawing on national fire, injury-cost and emergency department data, reports about 220 fire-related deaths a year in Canada from 2011 to 2020 and burn and fire injury costs of $299 million in 2018. In 2013, just over half (52.3%) of the burns recorded by the Canadian Hospitals Injury Reporting and Prevention Program (CHIRPP), an emergency department injury surveillance system, were scalds. The same chapter cites Canadian data (2001 to 2006, outside Quebec) showing disproportionately high age-standardized rates of hospitalization for fire-related injuries among children and youth aged 0 to 19 in areas where at least 33% of residents identified as First Nations or Métis, especially First Nations and Métis children under 10 (Wallace et al., 2025). These differences reflect housing, income and access to services, not the people themselves (Chapter 2). This book follows the OCAP® principles (ownership, control, access and possession) for First Nations data (Chapter 2).

Burn depth is described by the layers of skin destroyed (Table 35.4; Figure 35.11).

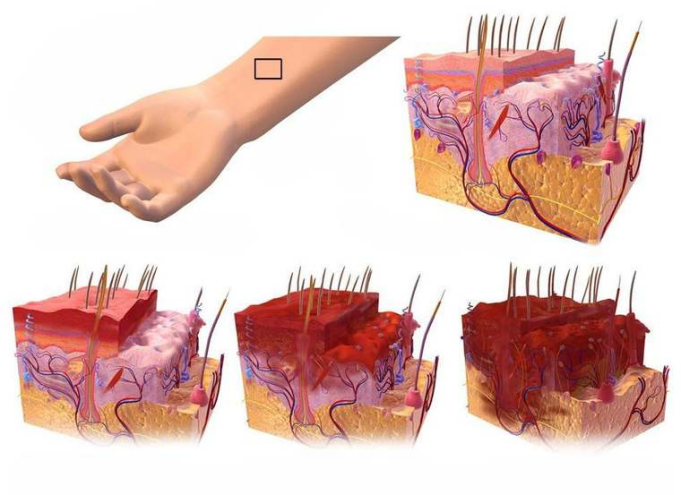

Figure 35.11 Classification of burn depth: superficial (first degree, affecting the epidermis), partial thickness (second degree, extending into the dermis with blisters), and full thickness (third degree, destroying all epidermal and dermal layers into subcutaneous tissue). (credit: "Figure 8.14, Burn Depth" by Persian Poet Gal/OpenStax, Clinical Nursing Skills, CC BY 3.0)] A **superficial burn** involves only the epidermis. A **partial-thickness burn** extends into the dermis: a superficial partial-thickness burn involves the upper dermis, and a deep partial-thickness burn reaches deeper into it. A **full-thickness burn** destroys the epidermis and the whole dermis and can extend to fat, muscle, tendon or bone (Wallace et al., 2025). Older terms number these as first, second and third degree, with fourth degree used when muscle or bone is involved (Trauma New Brunswick, 2025). Depth is hard to judge: even burn experts are accurate only 64% to 76% of the time, so early estimates are rechecked (Wallace et al., 2025). Healed superficial partial-thickness burns can stay sensitive to sun, cold and friction for months, and they may itch (Wallace et al., 2025). Redness and blanching can be harder to see on darker skin, so the nurse also notes blisters, moisture, texture, capillary refill and sensation (Black & Simende, 2020).

Table 35.4 Burn depth compared (Jeschke et al., 2020; Trauma New Brunswick, 2025; Wallace et al., 2025; original wording)

Depth	Layers involved	Appearance and feel	Pain	Usual healing
Superficial	Epidermis only	Red; skin intact; blanches; no blisters	Painful, from itching to sharp	Heals without surgery
Superficial partial-thickness	Epidermis and upper dermis	Pink to red; thin-walled blisters; blanches with brisk capillary refill	Very painful	Needs dressings and wound care; may scar; no surgery
Deep partial-thickness	Epidermis and deeper dermis	Mottled or cherry red; blanching reduced or absent; sluggish refill; thick-walled blisters possible	Varies; deep pressure felt, pinprick may not be	Usually needs surgery; will scar
Full-thickness	All layers of skin, sometimes deeper	White, pale, leathery, dry or charred (eschar); does not blanch	Little or no pain in the centre; may hurt at the edges	Needs surgery unless very small

First Aid and Emergency Care

The first step is to stop the burning and remove the person from the source safely (Trauma New Brunswick, 2025). Wounds Canada advises cooling thermal burns for 20 minutes, with clean running water at a tepid temperature or with wet towels and compresses, and never using ice or very cold water, which narrow the blood vessels. Early cooling helps keep the burn from becoming deeper

(Wallace et al., 2025). Cooling must not make the person cold. Trauma New Brunswick's emergency consensus accepts cooling with cool tap water for up to 30 minutes for burns of 5% of total body surface area or less, and it puts keeping the person warm ahead of applying dressings in the acute phase (Trauma New Brunswick, 2025). Clothing, jewellery and piercings are removed before swelling starts. The burns are covered with clean, dry sheets, and in the emergency department dressings are not applied until the burn team has been consulted (Trauma New Brunswick, 2025).

Inhalation injury is damage to the airway and lungs from heat, smoke or toxic gases. The risk is highest after a fire in an enclosed space such as a house or car. Cues include soot in the nose or mouth, a hoarse voice, cough, wheezing, stridor (a high-pitched sound on breathing in), burns of the face or neck and singed nasal hairs, but not every patient has these signs (Beyene & Hayhurst, 2026). The upper airway can swell and close, so the nurse raises the head of the bed to a Fowler's or semi-Fowler's position, watches the airway closely and reports changes at once (Wallace et al., 2025). Stridor, respiratory distress, deep facial burns, burns inside the mouth and a change in level of consciousness are among the reasons the team may need to secure the airway early (Trauma New Brunswick, 2025). Inhalation injury also increases the risk of pneumonia during mechanical ventilation, the volume of fluid needed and the risk of death (Jeschke et al., 2020).

Carbon monoxide poisoning is a common danger after smoke exposure. Carbon monoxide binds to hemoglobin and forms carboxyhemoglobin, which cannot carry oxygen. Pulse oximetry is unreliable in carbon monoxide poisoning: carboxyhemoglobin falsely raises the reading, so it can look normal while tissues are short of oxygen (Beyene & Hayhurst, 2026). Headache, nausea and confusion are cues. Oxygen at 15 L/min by non-rebreather mask is started at the first point of care, and blood tests include a carboxyhemoglobin level (Trauma New Brunswick, 2025). On 100% oxygen, the carboxyhemoglobin level falls by half in about an hour (Beyene & Hayhurst, 2026). Burning plastics can also release cyanide, which is suspected when shock and acid build-up in the blood persist despite oxygen and fluids (Trauma New Brunswick, 2025).

Total body surface area (TBSA) burned is estimated by adding only partial-thickness and full-thickness areas; superficial burns are not counted. The **rule of nines** divides the adult body into areas worth 9% or a multiple of 9%. For scattered burns, the person's palm and fingers equal about 1% of their TBSA. The **Lund and Browder chart** is the most accurate method and is preferred for children (Trauma New Brunswick, 2025; Wallace et al., 2025; Figure 35.12).

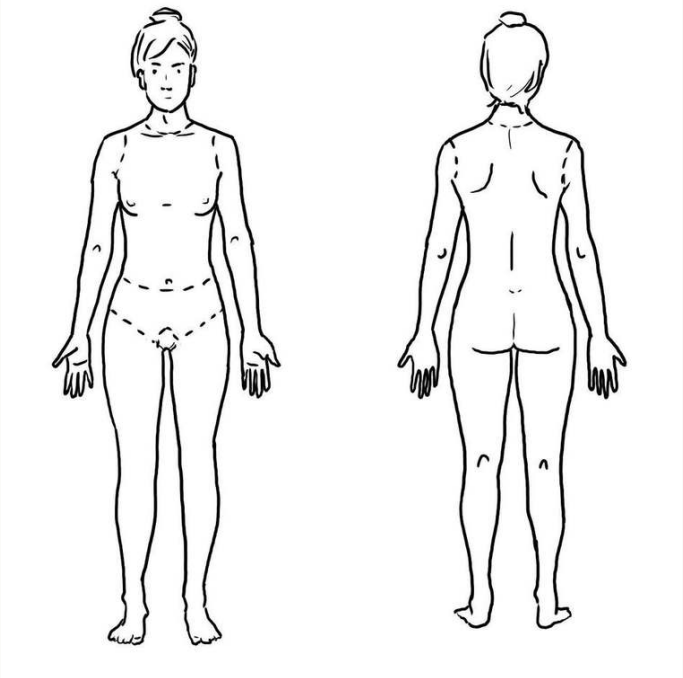

Figure 35.12 Body regions used in the adult Wallace rule of nines: the head and neck and each upper limb are 9% each, the anterior trunk, posterior trunk and each lower limb are 18% each (9% front and 9% back), and the perineum is 1%.

The American Burn Association (ABA) referral guidelines, which Canadian programs also use, list situations that call for immediate consultation with a burn centre and consideration of transfer. These include full-thickness burns; partial-thickness burns of 10% TBSA or more; deep burns of the face, hands, feet, genitals, perineum or joints; any suspected inhalation injury; all chemical burns; high-voltage electrical injury (1,000 volts or more) and lightning; burns with other injuries or serious health conditions; and pain that is hard to control. Smaller partial-thickness burns, any burn that may be deep and low-voltage electrical injuries still call for a consultation, and people with low-voltage injuries may need burn centre follow-up to check for symptoms that start later and for vision problems. The ABA states that its guidelines are meant to aid referral decisions and do not replace professional judgment (American Burn Association [ABA], 2025; Trauma New Brunswick, 2025).

After a high-voltage injury, a 12-lead electrocardiogram (ECG) and 24 hours of cardiac monitoring are indicated, and the team watches for compartment syndrome and muscle breakdown (rhabdomyolysis), with blood tests for creatine kinase and urine tests for myoglobin. For chemical

burns, staff first protect themselves with personal protective equipment, remove contaminated clothing, brush off any dry powder and then rinse the skin continuously with water. A poison centre can advise on specific chemicals (Trauma New Brunswick, 2025).

Burn Care in Hospital

A large burn causes fluid to leak from blood vessels into the tissues, which can lead to burn shock (Chapter 6). Adults with burns over 20% TBSA need planned fluid resuscitation with warmed lactated Ringer's solution and a urinary catheter to measure hourly urine output. Mortality rises if resuscitation is delayed more than 2 hours after a major burn (Trauma New Brunswick, 2025); the details are in the Going Deeper box. The nurse also watches circulation in limbs with deep burns that go all the way around (circumferential burns), because stiff, dead tissue called eschar (section 35.3) can act like a tourniquet as the tissues swell. Cool skin, slow or absent capillary refill, tense compartments and a clawed hand are warning signs; absent pulses are a late sign (Wallace et al., 2025). Deep burns around the chest or neck can limit breathing (Trauma New Brunswick, 2025). An **escharotomy**, a surgical cut through the eschar, releases the pressure.

Pain is severe. In the emergency phase, intravenous analgesia is given early in small, repeated doses; intramuscular opioids are avoided in burns over 10% TBSA because absorption is unreliable (Trauma New Brunswick, 2025). Pain and anxiety at dressing changes are planned for (Chapter 5). Burn survivors may also have itching as wounds heal (Wallace et al., 2025).

The burn team chooses the dressings. Deep partial-thickness and most full-thickness burns need surgery (Jeschke et al., 2020; Wallace et al., 2025): early removal of dead tissue (excision) followed by a **skin graft**, healthy skin moved from another part of the body (the donor site) to cover the wound. Sepsis is the leading cause of death in people with burns (Wallace et al., 2025), so strict infection prevention is essential (Chapter 4). Sepsis is harder to recognize after a major burn, and standard sepsis definitions miss some cases (Jeschke et al., 2020). Antibiotics are not given to prevent infection, and burns are treated as tetanus-prone wounds (Trauma New Brunswick, 2025). Tetanus immunization follows the Canadian Immunization Guide: for wounds other than clean, minor ones, a tetanus booster is given if 5 or more years have passed since the last dose, and tetanus immune globulin is added for people with fewer than three doses or an unknown history (Public Health Agency of Canada [PHAC], 2026).

A major burn sets off a hypermetabolic response that raises energy use and breaks down muscle and can last up to 36 months (Jeschke et al., 2020). Wounds Canada recommends starting nutrition early, ideally within 24 hours and no later than 48 hours, and keeping the room warm to reduce energy loss (Wallace et al., 2025; section 24.1). A core (internal) temperature below 36.5 °C counts as hypothermia in a person with burns (Trauma New Brunswick, 2025).

Recovery depends on a team. At Ontario's main adult burn centre, burn surgeons and nurses work with dietitians, pharmacists, physiotherapists, occupational and respiratory therapists, speech-language pathologists and social workers (Sunnybrook Health Sciences Centre, n.d.). Burns that heal by scarring tighten over joints. A **contracture** is a shortening of skin and tissue that limits movement. Occupational therapists and physiotherapists use positioning, splints, stretching and exercise to keep full range of motion, and many survivors wear compression garments for several years (Wallace et al., 2025). Raised (hypertrophic) scars develop in 30% to 90% of people with burns, and keloids occur mainly in people with darker skin (Jeschke et al., 2020). Anxiety, depression and post-traumatic stress symptoms are common and lower quality of life (Jeschke et al., 2020), so the nurse asks about mood, sleep, body image and peer support. Before discharge, the team plans wound care, follow-up (sometimes by telemedicine for rural and remote communities) and a return to work and daily life (Wallace et al., 2025). Prevention teaching matters: Wounds Canada reports that residential fires with no life-safety system present or working, such as a smoke alarm or sprinkler, accounted for 80% of deaths in residential fires (Wallace et al., 2025).

GOING DEEPER

Fluid Resuscitation After a Major Burn

Required for RN students; optional for PN students.

The ABA's 2024 burn shock resuscitation guideline covers adults with burns of 20% TBSA or more. It recommends that clinicians consider starting fluid at 2 mL/kg/%TBSA burned, lower than the older 4 mL/kg/%TBSA, to reduce total volume (Cartotto et al., 2024). Trauma New Brunswick's 2025 consensus applies this approach: the 24-hour estimate is 2 mL of lactated Ringer's × weight in kilograms × %TBSA, and the starting hourly rate is the 24-hour estimate divided by 16, which gives half the estimate in the first 8 hours if unchanged. Electrical injuries start at 4 mL instead of 2 mL (Trauma New Brunswick, 2025).

The formula only sets the starting rate; the burn team adjusts it hourly, mainly to urine output. The ABA recommendations set no adult urine output target; the guideline's text calls 0.5 mL/kg/h the standard target, and studies it reviewed aimed for 0.5 mL/kg/h or 30 to 50 mL/h (Cartotto et al., 2024). The Canadian consensus sets 30 to 50 mL/h for adults (75 to 100 mL/h when an electrical injury causes dark, myoglobin-stained urine) and adjusts the rate by up to one-third when output is more than one-third off target, in consultation with the physician (Trauma New Brunswick, 2025).

Too little fluid leads to organ failure and death. Too much, sometimes called fluid creep, causes edema, pulmonary edema and compartment syndromes of the abdomen, limbs and eye sockets (orbits); the guideline recommends selective monitoring of pressure inside the abdomen and eyes and suggests considering albumin, especially in larger burns (Cartotto et al., 2024). The nurse measures urine output every hour and reports output outside the target promptly so the team can adjust the rate.

CANADIAN CONTEXT

Burn Care Across Canada

Canada has far fewer burn centres than trauma centres: in 2010, there were about three adult trauma centres (levels 1 and 2) for every burn centre (Bell et al., 2012). In Ontario, Sunnybrook's Ross Tilley Burn Centre in Toronto provides tertiary care for most people with burn injuries in the province. About 70% of its patients come from outside the Greater Toronto Area, arriving by ambulance, plane or helicopter (Sunnybrook Health Sciences Centre, n.d.). A British Columbia study found that nearly 40% of that province's population would need transport over hundreds or thousands of kilometres to reach one of its two adult burn centres. People burned in rural areas had higher total mortality, but patients first treated at another hospital and then transferred had outcomes similar to those taken directly to a burn centre (Bell et al., 2012). Good early care in the first hospital therefore matters.

In rural, remote and northern communities, distance, weather and time of day affect transfer by helicopter or fixed-wing aircraft (Bell et al., 2012). Burn centres can support local teams with consultation, and follow-up assessments can be done by telemedicine (Wallace et al., 2025). Provincial systems differ; in New Brunswick, emergency teams consult through a provincial trauma line (Trauma New Brunswick, 2025). Housing and other social determinants of health shape both burn risk and recovery (Wallace et al., 2025; Chapter 2).

35.6 Skin Cancer and Other Common Skin Conditions

Nurses see more of a patient's skin than almost anyone else on the care team. A bath, a position change or a skin check for pressure injury is a chance to notice a lesion that is new or changing.

Skin Cancer

Non-melanoma skin cancer is diagnosed more often than any other cancer in Canada, but most cancer registries do not collect data on it because it is usually diagnosed and treated in a doctor's office. **Basal cell carcinoma** starts in the round basal cells at the bottom of the epidermis and makes up about 75% to 80% of skin cancers. **Squamous cell carcinoma** starts in the flat squamous cells of the outer epidermis and makes up about 20%. Basal cell carcinoma usually grows slowly and is often found early, and non-melanoma skin cancers rarely spread. Actinic keratosis is a precancerous skin condition that may become cancer if it is not treated (Canadian Cancer Society, 2024, n.d.-c).

Melanoma starts in melanocytes, the skin cells that make the pigment melanin, and is less common than non-melanoma skin cancer (Canadian Cancer Society, n.d.-b). For 2026, the Canadian Cancer Society estimates 11,300 new melanoma diagnoses in Canada (6,200 in men and 5,100 in women) and 1,250 deaths from melanoma (820 men and 450 women) (Brenner et al., 2026; Canadian Cancer Society, 2026). The Canadian Cancer Society teaches the ABCDE warning signs of a mole: **A**symmetry, when one half does not match the other; an irregular **B**order that is jagged, notched or blurry; uneven **C**olour, with shades of tan, brown and black; a **D**iameter larger than 6 mm, roughly the width of a pencil eraser; and **E**volving, meaning a change in colour, size, shape or feel, or new itching, burning or tingling. A sore that does not heal, oozes or bleeds is also a warning sign (Canadian Cancer Society, n.d.-a).

Acral melanoma is the most common type of melanoma in people with darker skin. It grows on the palms, the soles of the feet and the nails, areas that get little sun, and, unlike other melanomas of the skin, is not linked to ultraviolet (UV) exposure. Under a nail, it can appear as a dark streak running toward the nail fold. It is often diagnosed late, partly because patients and clinicians are less aware of it and most public education images show light skin; the ABCDE signs are less useful for these lesions (Nadelmann et al.,

2025). During care, the nurse looks at the soles, between the toes and at the nails of every patient, asks whether any spot is new or changing, and reports what they find (Figure 35.13).

Figure 35.13 Acral lentiginous melanoma: (a) a large asymmetric pigmented lesion with irregular borders and varied brown-to-black colour on the sole of the foot; (b) subungual melanoma of the thumb. Checking the palms, soles and nail beds is part of a complete skin assessment across all skin tones. (credit: (a) "Photography of a large acral lentiginous melanoma" by José C. C. Xavier-Júnior et al./Diagnostic Pathology, CC BY 4.0; (b) "Melanoma of thumb" by Wawjak/Wikimedia Commons, CC BY 4.0)

Sun protection is the main way to prevent most skin cancers. Health Canada advises protecting the skin whenever the UV Index is 3 or higher, even on cloudy days: staying out of the sun from 11 a.m. to 3 p.m., using shade, wearing long sleeves, long pants, a wide-brimmed hat and sunglasses that block UVA and UVB rays, and using a broad-spectrum, water-resistant sunscreen with a sun protection factor (SPF) of at least 30. Tanning equipment damages the skin and raises the risk of melanoma (Health Canada, 2023). Skin cancer risk after a kidney transplant is covered in Chapter 27, and cancer care in general in Chapter 9.

Other Common Conditions

Herpes zoster (shingles) is a reactivation of the varicella-zoster virus, which stays in the nerve roots after chickenpox. Tingling or pain begins 1 to 5 days before a rash of blisters appears in a band on one side of the body, usually without crossing the midline (MacFadden & Gold, 2012). Its risk rises with age as the immune system weakens, and with immune suppression; the lifetime risk in the general population in Canada may be as high as 30% (Krishnan et al., 2026). The most common complication is pain lasting more than 30 days after the rash begins, called postherpetic neuralgia. Antiviral medicines, such as valacyclovir, work best when started within 72 hours of the rash appearing; antivirals are started for zoster near the eye even after 72 hours, to reduce eye complications (MacFadden & Gold, 2012). The Canadian Immunization Guide recommends a two-dose series of the recombinant zoster vaccine for adults 50 and older without contraindications and for adults aged 18 and older whose immune systems are, or will be, suppressed (Krishnan et al., 2026; PHAC, 2025; Figure 35.14).

Psoriasis is a chronic inflammatory skin condition that affects about 1 million people in Canada. It causes raised patches (plaques) that look red to violet depending on the person's skin tone. It is not contagious. About one in three people with psoriasis can develop psoriatic arthritis (Chapter 34), and psoriasis is linked with a higher risk of heart attack, stroke and depression. Stigma, embarrassment and discomfort can lower quality of life (Canadian Dermatology Association, 2026b). **Atopic dermatitis** is a form of eczema, the name for a group of conditions that inflame the skin. Up to 17% of people in Canada are estimated to have it at some point in life, and on darker skin it often looks ashen brown or greyish rather than red (Canadian Dermatology Association, 2026a). A Canadian consensus guideline advises assessing severity with both clinician measures and the person's own report of symptoms, teaching people to avoid triggers and use moisturizers, and limiting topical corticosteroids to short, intermittent courses (Gooderham et al., 2025). For both conditions, the nurse asks how the skin affects sleep, work and mood, and avoids reacting to visible skin in ways that add to stigma.

SCOPE IN PRACTICE

Skin and Wound Care and Who Does What

Every nurse assesses skin, prevents pressure injuries and skin tears, and reports wounds that are new, worse or infected. Who does more depends on authority, competence and context (College of Nurses of Ontario [CNO], 2025; Chapter 1, section 1.3).

- **Authority:** In Ontario, RNs and RPNs are authorized to perform the controlled act of a prescribed procedure below the dermis, such as packing a deep wound, and nurses may initiate such wound care without an order where the regulation's conditions are met and the setting allows. Nurses cannot initiate controlled acts in public hospitals, where an order is needed (CNO, 2025).
- **Competence:** Choosing dressings, managing negative pressure wound therapy and conservative sharp debridement (removing dead tissue with sterile instruments) need specific knowledge, skill and judgment. Wounds Canada wants policies and education in place before NPWT is used (Tecson et al., 2025), and Nurses Specialized in Wound, Ostomy and Continence Canada (NSWOCC, 2021) recommends advanced education and a clinical preceptorship before sharp debridement. A nurse without that education asks for support.
- **Context:** Employer policies set which nurses may do advanced wound skills (NSWOCC, 2021); employers can limit but not expand a nurse's legislated scope (CNO, 2025). Wound care specialists help where available.

Any nurse who notices spreading infection, dehiscence, evisceration or signs of sepsis acts at once and escalates; the RPN consults the RN as the patient's needs change. Rules differ by province and territory, and CNO's revised Scope of Practice standard takes effect on March 1, 2027 (CNO, 2026).

PATIENT EDUCATION

Caring for Your Incision at Home

- Wash your hands before and after you touch your incision or dressing.
- Keep the dressing on for as long as your team tells you. Most people can shower 48 hours after surgery, but ask your surgeon first.
- Stitches or staples usually come out 1 to 2 weeks after surgery. Keep that appointment.

- Hold a pillow firmly over a belly or chest incision when you cough, sneeze or get up. Follow your team's advice on lifting and activity.
- You may feel a firm ridge under the incision in the first week or so. This is normal healing.
- Call your surgeon or clinic the same day if you notice pain that gets worse instead of better; swelling or warmth that spreads; a change in skin colour around the incision that spreads (red on lighter skin; on darker skin, a patch darker than your usual skin); drainage that is cloudy, smelly or increasing; edges that pull apart; or a fever.
- Call 9-1-1 if the incision opens and you can see tissue underneath, or if you feel faint or confused.
- New scars on lighter skin often turn pink, then white or silver. On darker skin, scars may become darker than your usual skin colour.

Keep your team's phone numbers handy, and ask for information in the language you read best (Tecson et al., 2025; WUWHS, 2018).

Chapter 35 Summary

35.1 Skin Structure and Assessment

- Skin has three layers: the epidermis, the dermis and the fatty hypodermis. With age, skin thins, its layers separate more easily, and it heals more slowly.
- Skin assessment must work on every skin tone: good lighting, a recorded baseline skin tone, comparison with the other side, and touch for warmth, firmness and moisture, together with the person's own report of pain or change.
- Redness may not be visible on darker skin; inflammation may show as a patch darker than the person's usual skin, or may be found mainly by touch.
- Moisture-associated skin damage, including incontinence-associated dermatitis, is prevented and treated by gentle cleansing, a barrier product and moisturizing, plus control of the source of moisture.
- Skin tears are classified by ISTAP as Types 1 to 3 and are prevented by twice-daily moisturizing and gentle handling; they are dressed with silicone dressings marked for direction of removal, not adhesive strips.

35.2 Pressure Injuries

- Pressure injuries result from pressure or pressure with shear, often beginning deep near the bone; moisture and heat at the skin surface add to the risk.
- Prevention combines risk screening with a tool the employer chooses plus clinical judgment, regular skin checks, repositioning on a written schedule, heel offloading, support surfaces, moisture management, nutrition and teaching.
- Stages 1 to 4, unstageable and deep tissue pressure injury are defined by the deepest tissue involved; stages are never reversed as a wound heals.
- On darker skin, a deep tissue pressure injury may not look purple or maroon and may be found mainly by temperature, firmness and pain.
- Care starts with removing the cause; stage 3, stage 4, unstageable and non-improving injuries are referred to the wound care team.

35.3 Wound Healing and Wound Care

- Wounds heal through hemostasis, inflammation, proliferation and remodelling, by primary, secondary or delayed primary intention; chronic wounds stall because a barrier to healing persists.
- Wound bed preparation starts with the cause and the person, then decides whether the wound is healable, maintenance or non-healable, which sets the goal of care.
- Wound assessment covers location, size, undermining and tunnelling, wound bed tissue, exudate, edges, surrounding skin, pain and odour, measured the same way each time.

- Healable wounds need moisture balance; maintenance and non-healable wounds need moisture and bacterial reduction, and stable dry eschar is left in place.
- Local, spreading and systemic infection differ in their signs; spreading or systemic signs are reported promptly using SBAR, and swabs follow the Levine technique when ordered.

35.4 Surgical Wounds and Skin Infections

- A closed incision should be sealed by about day 4, with a healing ridge along its whole length between days 5 and 9; drainage after day 9 is not expected.
- Signs of surgical site infection include new or increasing pain, spreading warmth and swelling, cloudy or foul-smelling drainage and fever; on darker skin, colour change may not show.
- Dehiscence is separation of the incision; evisceration is a surgical emergency in which the nurse stays, calls for help, covers the organs with sterile saline-moistened gauze and positions the patient in low Fowler's with the knees bent.
- Cellulitis causes warmth, swelling, tenderness and a spreading colour change; the nurse marks the edge, records warmth and swelling, elevates the limb and escalates signs of sepsis.
- Pain out of proportion to the skin findings, rapid spread and hard tissue beyond the visible change suggest a necrotizing soft tissue infection, which needs urgent surgery.

35.5 Burns

- Burns are classified as superficial, superficial partial-thickness, deep partial-thickness or full-thickness; only partial-thickness and full-thickness areas count toward TBSA.
- First aid is to stop the burning, cool with tepid running water for about 20 minutes without ice, remove jewellery, cover with clean dry sheets and keep the person warm.
- After a fire in an enclosed space, soot, a hoarse voice and stridor point to inhalation injury; pulse oximetry can be falsely normal in carbon monoxide poisoning, so high-flow oxygen is given and carboxyhemoglobin is measured.
- ABA criteria call for immediate burn centre consultation for full-thickness burns, partial-thickness burns of 10% TBSA or more, deep burns of the face, hands, feet, genitals, perineum or joints, inhalation injury, chemical burns and high-voltage injuries.
- Adults with burns over 20% TBSA receive planned fluid resuscitation that the burn team adjusts to hourly urine output.
- Hospital care includes pain control, surgery and grafting, infection prevention, early nutrition, warmth, contracture prevention and mental health support.

35.6 Skin Cancer and Other Common Skin Conditions

- Non-melanoma skin cancer is the most common cancer in Canada; an estimated 11,300 people will be diagnosed with melanoma in 2026 and 1,250 will die from it.
- The ABCDE signs (asymmetry, border, colour, diameter, evolving) guide what to report; acral melanoma on the palms, soles and nails is the most common type in people with darker skin.
- Health Canada advises sun protection whenever the UV Index is 3 or higher, including broad-spectrum, water-resistant sunscreen with an SPF of at least 30.
- Shingles antivirals work best within 72 hours of the rash; the Canadian Immunization Guide recommends two doses of the recombinant zoster vaccine for adults 50 and older.
- Psoriasis and atopic dermatitis are long-term conditions that can lower quality of life; care includes skin care, treatment as prescribed and a non-stigmatizing approach.

Key Terms (56)

abscess: A walled-off collection of pus in the skin or the tissue beneath it, treated mainly by incision and drainage.

acral melanoma: A type of melanoma on the palms, soles or nails that is not linked to ultraviolet exposure; the most common type in people with darker skin.

basal cell carcinoma: The most common skin cancer, starting in the basal cells of the epidermis; it usually grows slowly and rarely spreads.

biofilm: A complex community of bacteria and fungi held together on a wound in a slimy coating made of sugars and proteins; it delays healing and cannot be detected by standard culture.

burn: Damage to the skin or deeper tissues caused by heat, chemicals, electricity, radiation, friction or extreme cold.

carbon monoxide poisoning: Harm caused when inhaled carbon monoxide binds to hemoglobin and forms carboxyhemoglobin, which cannot carry oxygen; pulse oximetry can read falsely normal.

cellulitis: A spreading infection of the skin and the tissue just beneath it, causing warmth, swelling, tenderness and a spreading change in colour.

chronic wound: A wound, also called a wound of long duration, that has stalled in healing because a barrier to healing has not been corrected.

contracture: A shortening of scarred skin and tissue that limits the movement of a joint.

deep tissue pressure injury (DTPI): A pressure injury that starts near the bone and shows as persistent, non-blanching discolouration or a blood blister; on darker skin it may not look purple or maroon.

dehiscence: Partial or complete separation of the edges of a closed surgical incision.

delayed primary intention: Closure of a contaminated wound after it has been left open for several days.

dermis: The layer of skin beneath the epidermis that contains collagen and elastic fibres, capillaries, nerve endings, hair follicles and glands.

device-related pressure injury: A pressure injury caused by a medical device, usually shaped like the device, and staged with the same system as other pressure injuries.

epidermis: The thin outer layer of skin, without its own blood vessels, that forms a waterproof barrier and contains the pigment-making melanocytes.

eschar: Dry, dark, leathery dead tissue in a wound.

escharotomy: A surgical cut through the eschar of a deep circumferential burn to relieve pressure on a limb, the chest or the neck.

evisceration: Protrusion of organs, such as bowel, through a separated abdominal incision; a surgical emergency.

exudate: Fluid that drains from a wound.

fluid resuscitation: Planned intravenous fluid given after a major burn to replace fluid that leaks out of the blood vessels, adjusted to urine output.

full-thickness burn: A burn that destroys the epidermis and the whole dermis and may extend deeper; it looks white, leathery or charred and has little pain at its centre.

granulation tissue: Moist, bumpy new connective tissue with many capillaries that fills a wound from its base during healing.

healing ridge: A firm band of new collagen that can be felt under a healing incision, normally along its whole length between days 5 and 9.

herpes zoster: Reactivation of the varicella-zoster virus, causing pain and a band of blisters on one side of the body; also called shingles.

hypodermis: The fatty subcutaneous layer beneath the dermis that insulates, cushions and stores energy; it has a poor blood supply.

incontinence-associated dermatitis (IAD): A form of MASD caused by urine, stool or both, usually affecting the perineum, buttocks and upper inner thighs.

induration: Hardening of tissue that can be felt on palpation, often a sign of inflammation or deep damage.

inhalation injury: Damage to the airway and lungs from heat, smoke or toxic gases, suspected after a fire in an enclosed space.

Lund and Browder chart: A body diagram used to estimate the percentage of body surface burned; the most accurate method and the preferred one for children.

melanoma: A cancer that starts in melanocytes, the skin cells that make the pigment melanin; less common than non-melanoma skin cancer.

microclimate: The conditions, especially moisture and warmth, at the skin where it meets a surface such as a mattress or chair.

moisture balance: Keeping a healable wound moist enough for cells to migrate but not so wet that the edges macerate.

moisture-associated skin damage (MASD): Inflammation and erosion of skin caused by long contact with urine, stool, sweat, wound drainage or stoma output.

mucosal membrane pressure injury: A pressure injury on a moist lining, such as the lips or nose, where a device has been used; it cannot be staged.

necrotizing soft tissue infection: A rapidly spreading infection that destroys deep tissues such as fat and fascia; a surgical emergency.

negative pressure wound therapy: Wound treatment that uses a sealed dressing connected to a pump that applies suction to the wound.

offloading: Removing pressure from an area of the body completely, for example by floating the heels off the bed.

partial-thickness burn: A burn that destroys the epidermis and part of the dermis; superficial partial-thickness burns blister and are very painful, and deep partial-thickness burns usually need surgery.

postherpetic neuralgia: Pain lasting more than 30 days after the rash of herpes zoster begins.

pressure injury: Localized damage to skin and underlying soft tissue, usually over a bony prominence or under a device, caused by pressure or pressure combined with shear.

primary intention: Healing of a wound whose edges have been brought together with sutures, staples or tape, without the need to fill with granulation tissue.

rule of nines: A method of estimating the burned body surface in adults that divides the body into areas of 9% or multiples of 9%.

secondary intention: Healing of an open wound that fills with granulation tissue from the base up.

shear: The force created when deeper tissue slides in one direction while the skin is held in place by a surface, distorting tissue and blood vessels.

skin graft: Healthy skin moved from one part of the body (the donor site) to cover a wound.

skin tear: A traumatic wound caused by mechanical force, such as handling or adhesive removal, that does not go through the subcutaneous layer; classified as ISTAP Type 1, 2 or 3.

slough: Soft, moist dead tissue in a wound that may be yellow, tan or grey.

squamous cell carcinoma: A skin cancer that starts in the flat squamous cells of the outer epidermis.

superficial burn: A burn involving only the epidermis; the skin is intact, painful and without blisters.

support surface: A mattress, overlay or cushion designed to redistribute pressure; it does not replace repositioning.

surgical site infection: An infection of a surgical incision or of the deeper tissues or organ space after an operation.

total body surface area: The whole skin surface of the body, used as the basis for expressing the extent of a burn as a percentage (TBSA).

tunnelling: A narrow channel extending from a wound into deeper tissue.

undermining: Tissue destroyed under intact skin at a wound's edge, forming a shelf.

unstageable pressure injury: A full-thickness pressure injury whose depth cannot be seen because slough or eschar covers the base.

wound bed preparation: A framework for wound care that starts by treating the cause, addressing the person's concerns and deciding whether a wound can heal, then guides local care.

Licensure Review & Clinical Judgment Questions (40)

Questions tagged **[Core]** apply to all nursing students (NCLEX-RN, REx-PN, and CPNRE). Questions tagged **[RN]** draw on *Going Deeper* content.

Case: Mrs. Olive Bertrand (Questions 1–4): Mrs. Olive Bertrand, 79, has moderate dementia and was admitted to a medical unit in Ontario five days ago with a urinary tract infection. She needs help to turn, is incontinent of urine and stool, and eats about one-quarter of each meal. Today the RPN finds a shallow, open area over the sacrum with a moist pink base and no slough, about 2 cm by 1.5 cm. The surrounding skin is intact.

1. [CORE] The RPN plans care to prevent further pressure damage to Mrs. Bertrand's sacrum. Which plan is most appropriate?

a. Keep her on her back with the head of the bed raised to 45 degrees so that she can watch television and stay more oriented to the day

b. Turn her off her sacrum on a written schedule, using a lift sheet to move her and keeping the head of the bed low when possible

c. Reduce repositioning to once a shift now that she has a pressure redistribution mattress, to avoid waking her during the night

d. Sit her up in a chair for most of the day without a cushion, because getting her out of bed removes pressure from the sacrum

Answer: b — A written repositioning schedule that keeps her off the injured area, moving her with a lift sheet to limit friction and shear, and a low head of bed to limit sliding, follows Wounds Canada's recommendations (section 35.2, Prevention). Option a raises the head of the bed well above about 30 to 35 degrees and keeps weight on the sacrum, increasing shear and pressure. Option c is wrong because a support surface reduces pressure but does not replace repositioning. Option d moves the pressure to the sacrum and buttocks while seated; a person at risk who sits needs a pressure-redistributing cushion and regular weight shifts.

2. [CORE] After an episode of fecal incontinence, which skin care does the RPN provide for Mrs. Bertrand?

a. Wash the area with bar soap and a washcloth, scrubbing firmly to remove all stool, and leave the skin open to air until it is dry

b. Apply a hydrogel to the perineum and buttocks so the skin stays moist and does not crack between episodes of incontinence

c. Cover the buttocks and the sacral wound with a thick layer of zinc oxide paste so that a separate wound dressing is not needed

d. Cleanse gently with a pH-balanced, soap-free cleanser, pat dry, and apply a barrier product to the surrounding intact skin

Answer: d — Wounds Canada's approach to incontinence-associated skin damage is to cleanse gently with a pH-balanced, soap-free cleanser, pat dry, protect with a barrier and restore with a moisturizer (section 35.1, Moisture and Fragile Skin). Option a uses alkaline soap and friction, which further damage fragile skin. Option b adds moisture; moisture-donating products such as hydrogels are not recommended for moisture-associated skin damage. Option c treats an open stage 2 wound as if it were intact skin; the wound itself needs a moist, protective dressing, while barrier products protect the intact skin around it.

3. [CORE] Mrs. Bertrand continues to eat about one-quarter of her meals. Which action by the RPN is most appropriate?

a. Report her poor intake to the RN and suggest a nutrition screen and a referral to the dietitian, as nutrition supports healing

b. Wait until her urinary tract infection has been treated, because her appetite is likely to return on its own once she feels better

c. Encourage her daughter to bring in her favourite takeout meals, because the hospital diet does not need to change at all

d. Record her intake as "poor" each day so the team can review the pattern at discharge, since nutrition is not a skin issue

Answer: a — Poor intake is a risk factor for pressure injury and delays healing; Wounds Canada recommends nutrition screening with a validated tool and involving a dietitian, and the RPN consults the RN as the patient's needs change (sections 35.2 and 24.1). Option b delays action while a wound is already present. Option c may help her eat but ignores the need for a nutrition assessment, and family food may not meet her needs. Option d documents the problem without acting on it and is wrong about nutrition's role in skin health.

4. [CORE] Two weeks later, the sacral wound is smaller, 1.2 cm by 0.8 cm, with a pink moist base and new skin growing in from the edges. Which documentation entry by the RPN is most accurate?

a. "Sacral pressure injury now stage 1, 1.2 x 0.8 cm, pink and moist, no drainage, healing well; continue the same turning plan."

b. "Sacral wound improving and looks much better than last week; dressing changed; patient settled; family updated."

c. "Healing stage 2 pressure injury, sacrum, 1.2 x 0.8 cm, pink moist base, no drainage, periwound skin intact; turning plan continued."

d. "Sacral ulcer reversed to a stage 1 pressure injury, 1.2 x 0.8 cm, with good new tissue and no odour; patient tolerated care well."

Answer: c — A pressure injury keeps the stage it had when first assessed and is documented as a healing stage 2; good documentation records location, stage, size, wound bed, drainage, surrounding skin and the plan (section 35.2, Staging and Care, and section 35.3, Assessing a Wound). Options a and d use reverse staging, which is incorrect even though they include measurements. Option b is vague and gives no measurements or description that another nurse could compare with.

5. [CORE] A nurse is assessing the sacrum of a patient with dark brown skin who has been on bed rest for two days. Which finding is the strongest sign of early pressure damage?

a. The skin over the sacrum looks the same colour as the lower back under the room's fluorescent ceiling light

b. The skin over the sacrum is dry and slightly flaky, and the patient says it has felt this way for several months

c. An area over the sacrum feels warmer and firmer than nearby skin, and the patient says it is tender when touched

d. The skin over the sacrum blanches and returns to its usual colour within a few seconds after gentle fingertip pressure

Answer: c — On darker skin, redness may not be visible, so temperature, firmness or bogginess, and pain compared with nearby skin are key signs of early pressure damage (sections 35.1 and 35.2). Option a relies on colour alone under fluorescent light, which casts a bluish tint that can hide changes. Option b describes long-standing dry skin, not a new pressure change. Option d describes normal blanching, which suggests no pressure injury at this site.

6. [CORE] A student asks why older adults develop skin tears so easily. Which explanation by the nurse is most accurate?

a. "The ridges that anchor the outer skin layer to the layer below flatten with age, so the layers separate more easily."

b. "Older adults make more collagen in the dermis, which makes the skin stiff and likely to crack when it is moved."

c. "The outer skin layer thickens with age and loses its blood vessels, so it splits when it is pulled during a transfer."

d. "Older skin becomes more acidic over time, and the acid weakens the skin so it tears with even light pressure."

Answer: a — With age, the rete pegs that lock the epidermis to the dermis flatten, so the layers separate under friction and shear (section 35.1, How Skin Works). Option b is wrong because collagen declines, by about 1% a year. Option c is wrong because the epidermis thins with age, and it never has its own blood vessels. Option d is wrong because older skin becomes more alkaline, not more acidic.

7. [CORE] Which finding suggests incontinence-associated dermatitis rather than a pressure injury?

a. A single round wound with a defined edge directly over the bony part of the sacrum and coccyx

b. A purple area of intact skin over the heel in a patient who cannot move their legs

c. A deep crater on the hip with yellow slough at the base and tunnelling toward the bone

d. Diffuse, painful inflammation spreading across the perineum, buttocks and inner thighs

Answer: d — Incontinence-associated dermatitis is irritation from urine or stool that usually affects the perineum, buttocks and upper inner thighs, with inflammation and pain (section 35.1, Moisture and Fragile Skin). Options a, b and c describe damage over bony prominences that is typical of pressure injury: a defined wound over the sacrum, a possible deep tissue pressure injury on the heel, and a full-thickness injury on the hip.

8. [CORE] A resident bumps her forearm on a wheelchair arm. The nurse finds a skin tear with a flap that covers about half of the wound bed; the rest of the flap is missing. How does the nurse classify this skin tear?

a. ISTAP Type 1, because there is still a skin flap present at the wound

b. ISTAP Type 2, because part of the flap is lost and it cannot cover the whole bed

c. ISTAP Type 3, because the wound bed can be seen through part of the flap

d. A stage 2 pressure injury, because the wound is a partial-thickness loss of skin

Answer: b — In the ISTAP classification, Type 2 is partial flap loss: what remains of the flap is not enough to cover all of the wound bed (section 35.1, Moisture and Fragile Skin). Type 1 (option a) has no skin loss: the tear is linear or the flap can cover the whole bed. Type 3 (option c) is total flap loss with the entire bed exposed. Option d is wrong because skin tears are traumatic wounds classified by ISTAP; the pressure injury staging system is used only for pressure injuries.

9. [CORE] Which action is correct when the nurse dresses a Type 1 skin tear on an older adult's lower arm?

a. Close the wound edges with adhesive closure strips so that the flap stays firmly in place while it heals

b. Cover the area with a transparent film dressing so that staff can see the flap without removing the dressing

c. Ease the flap back into place, apply a silicone dressing and mark an arrow showing the direction of removal

d. Apply a povidone-iodine dressing to prevent infection, because older adults are at high risk of wound infection

Answer: c — ISTAP recommends easing a viable flap back into place, using a silicone dressing and marking the direction of removal so the flap is not lifted at the next change (section 35.1, Moisture and Fragile Skin). Adhesive closure strips (option a) are no longer preferred, films with acrylic or rubber adhesives (option b) are not recommended for people with or at high risk of skin tears, and iodine-based products (option d) should not be used for skin tears.

10. [CORE] A patient with a hip fracture is at high risk of heel pressure injury. Which action best protects the heels?

a. Float the heels clear of the mattress with a wedge-shaped cushion or heel-suspension device, keeping the Achilles tendon free of pressure

b. Place a folded towel directly under each heel so that the heels sink less deeply into the surface of the pressure redistribution mattress below

c. Massage the heels firmly with lotion every two hours to improve blood flow to the skin and the tissue that lies just under it

d. Rely on the pressure redistribution mattress alone, because the mattress spreads the patient's weight evenly across the heels

Answer: a — Heels are managed separately from the support surface and floated off the bed; a wedge-shaped cushion or device that suspends the heels is more effective than a standard pillow, and the Achilles tendon is protected (section 35.2, Prevention). Option b keeps pressure on the heel. Option c adds friction and force to tissue that may already be damaged and does not remove pressure. Option d is wrong because heels need separate offloading.

11. [CORE] A nurse assesses a sacral pressure injury. The wound is a full-thickness skin loss with yellow fat visible at the base and some slough at one edge. No muscle, tendon or bone can be seen or felt. How is the injury staged?

a. Stage 2, because the wound is moist and there is no eschar

b. Unstageable, because slough is present in part of the wound

c. Deep tissue pressure injury, because damage extends deeply

d. Stage 3, because fat is visible but deeper structures are not

Answer: d — A stage 3 pressure injury is full-thickness skin loss with fat visible, with or without slough, and no exposed bone, cartilage, tendon, ligament, muscle or fascia (section 35.2, Table 35.1). Option a is wrong because a stage 2 injury is partial-thickness with no visible fat or slough. Option b applies only when slough or eschar hides the depth; here the base is visible. Option c describes discolouration or a blood blister with or without intact skin, not an open wound with visible fat.

12. [CORE] A patient with peripheral arterial disease has a pressure injury on the heel covered with dry, black, firmly attached eschar. The surrounding skin shows no redness, swelling or drainage. Which action is most appropriate?

a. Apply a hydrogel and a moist dressing to soften the eschar so that it can be removed at the next dressing change

b. Keep the eschar dry and intact, offload the heel completely, and report and document the injury as unstageable

c. Gently lift the edge of the eschar with forceps to see how deep the wound is so that it can be staged accurately

d. Soak the foot in warm water twice a day so that the eschar loosens on its own and the wound can begin to heal

Answer: b — Stable eschar on a heel or a limb with poor blood flow (dry, attached, intact, with no redness or softness around it) acts as a natural cover and is not softened or removed; the injury is unstageable while the base is hidden, and the heel is offloaded (sections 35.2 and 35.3). Options a and d would soften the eschar and risk infection in a limb with poor blood supply. Option c removes protective eschar and is outside safe practice for staging.

13. [CORE] A patient receiving oxygen by nasal cannula for three days reports that the tops of both ears are sore. Which action is the priority?

a. Ask the respiratory therapist to switch the patient to a face mask, because masks do not cause pressure injuries on the face

b. Remove the oxygen to rest the skin for several hours, then reapply it once the soreness has completely settled

c. Inspect and palpate the skin under the tubing, pad or reposition the tubing as policy allows, and report findings

d. Record the complaint and reassess at the end of the shift, because pain under tubing is expected with oxygen use

Answer: c — Medical devices can cause pressure injuries, so the nurse checks the skin under and around every device and relieves pressure as policy allows (section 35.2, How Pressure Injuries Develop). Option a is wrong because any device, including a mask, can cause a device-related pressure injury. Option b stops prescribed oxygen, which may be unsafe. Option d delays assessment of a possible pressure injury.

14. [CORE] During a dressing change, the nurse sees soft, moist, yellow-tan tissue attached to part of the wound base. How does the nurse describe this tissue?

a. Slough, a soft, moist dead tissue that may be yellow, tan or grey

b. Eschar, a soft, moist tissue that signals the wound is healing well

c. Granulation, a yellow tissue that forms early in normal wound healing

d. Epithelium, new tissue that grows inward from the wound edges

Answer: a — Slough is soft, moist, dead tissue that may be yellow, tan or grey (section 35.2, Staging and Care). Option b is wrong because eschar is dry, dark, leathery dead tissue, and neither slough nor eschar shows healing. Option c is wrong because granulation tissue is moist, bumpy new tissue that is red or pink. Option d is wrong because new epithelium is thin new skin at the edges, not yellow tissue on the base.

15. [CORE] An RPN on a medical unit is changing the dressing on a patient's leg wound and notes that the area of warmth and swelling now extends about 4 cm beyond the wound edge. The patient's temperature is 38.4 °C. What is the RPN's most appropriate action?

a. Apply a silver dressing and reassess the wound at the next scheduled dressing change in two days

b. Document the findings and ask the next shift to measure the area again before calling anyone

c. Take a wound swab from the pus on the dressing and send it to the laboratory before reporting

d. Report the findings promptly to the RN and the prescriber using SBAR, and monitor for sepsis

Answer: d — Inflammation more than 2 cm beyond the wound edge with fever suggests spreading infection that needs prompt assessment and possible systemic treatment; the RPN reports promptly using SBAR, consults the RN as the patient's needs change, and watches for sepsis (section 35.3, Wound Infection; Chapters 4 and 6). Option a relies on a dressing for an infection that has spread beyond the wound. Option b delays escalation. Option c delays reporting, and a swab is taken as ordered by the Levine technique from cleansed viable tissue, not from pus.

16. [CORE] An RPN on a surgical unit in an Ontario public hospital is asked to pack a deep stage 4 sacral pressure injury that extends below the dermis. Using CNO's authority, competence and context, which statement is most accurate?

a. The RPN may pack the wound without an order, because wound care is a basic nursing skill for every nurse

b. The RPN may pack it with an order, if she has the competence and the employer's policy and setting allow it

c. The RPN may not pack the wound, because only an RN may perform any procedure below the dermis in Ontario hospitals

d. The RPN may pack the wound only if the wound care nurse is physically present for the entire procedure

Answer: b — Performing a prescribed procedure below the dermis is a controlled act that RNs and RPNs are authorized to perform with an order; the nurse must also have the competence, and employer policy and setting (context) must allow it (section 35.3; section 1.3). Option a is wrong because nurses cannot initiate controlled acts in a public hospital, so an order is needed. Option c is wrong because RPNs share this authority. Option d adds a requirement that is not part of CNO's standard; supervision may be set by employer policy but is not a general rule.

17. [CORE] Which actions help prevent pressure injuries in an adult admitted to hospital with reduced mobility? Select all that apply.

a. Screening pressure injury risk on admission with the tool the employer has chosen, and again when the patient's condition changes

b. Repositioning on a written schedule that is matched to the patient, using a lift sheet rather than dragging the patient up the bed

c. Floating the heels off the mattress with a device that suspends them, while keeping pressure off the Achilles tendon

d. Raising the head of the bed to 60 degrees at all times so that the patient does not slide down toward the foot of the bed

e. Stopping repositioning once the patient is placed on a pressure redistribution mattress, so that the patient can rest

f. Managing incontinence promptly by cleansing gently and applying a barrier product to protect the skin

Answer: a, b, c, f — Risk screening on admission and with change, an individualized repositioning schedule with lift sheets, heel offloading, and prompt moisture management are all recommended prevention measures (section 35.2, Prevention). Option d increases sliding and shear; the head of the bed is kept below about 30 to 35 degrees unless the patient's condition requires otherwise. Option e is wrong because support surfaces reduce pressure but do not replace repositioning.

18. [RN] An RN assesses the heel of a patient with deep brown skin who has been immobile after a stroke. The skin is intact and looks slightly darker than the other heel, with no purple or maroon colour. The area is firm and boggy, cooler than the other heel, and painful to touch. Which conclusion is most appropriate?

a. The findings suggest a deep tissue pressure injury, because colour change may be subtle on darker skin and firmness, temperature change and pain often come first

b. The findings rule out a deep tissue pressure injury, because that diagnosis requires a purple or maroon colour change that would be visible on any skin tone

c. The findings describe a stage 1 pressure injury only, because the skin is intact, and intact skin cannot have damage to deeper tissue below it

d. The findings are most likely from the stroke itself, because changes in temperature and sensation on the affected side are expected after a stroke

Answer: a — A deep tissue pressure injury may not appear purple or maroon on darkly pigmented skin; pain, temperature change and changes in firmness often come before visible colour change (section 35.2, Staging and Care; Table 35.1). Option b is wrong because the colour may not show on darker skin. Option c is wrong because a deep tissue pressure injury can occur under intact skin. Option d attributes new local findings to the stroke and misses a pressure injury that needs offloading and reporting.

19. [RN] An RN assesses a healable venous leg wound that has stalled for three weeks. Drainage has increased, the granulation tissue is bright red and bleeds easily, and there is a new odour. The surrounding skin is not warm, swollen or discoloured, and the patient has no fever. How does the RN interpret these findings?

a. Systemic infection that requires blood cultures and immediate intravenous antibiotics

b. Normal inflammation that is expected during the proliferative phase of wound healing

c. Local infection in the wound that may warrant a topical antimicrobial and reassessment

d. Spreading infection, because increased drainage means that bacteria have left the wound

Answer: c — Three or more NERDS signs (nonhealing, exudate increase, red friable granulation, smell) without surrounding warmth, swelling or systemic signs point to local infection, for which topical antimicrobial treatment and reassessment may be appropriate (section 35.3, Wound Infection; Going Deeper box). Option a would need systemic signs such as fever or malaise. Option b is wrong because inflammation should settle after about four days and friable granulation is not normal. Option d is wrong because spreading infection involves signs beyond the wound edge, such as inflammation more than 2 cm from the edge.

20. [RN] An RN cares for a patient with severe peripheral arterial disease and no surgical options who has a dry wound on the toe. The vascular team has documented the wound as non-healable. Which plan fits wound bed preparation principles?

a. Apply a hydrogel and a moisture-retentive dressing to promote moist healing and encourage the growth of granulation tissue

b. Request sharp debridement at the bedside to remove all dead tissue so that the wound bed can be fully prepared for moist healing

c. Change to an absorbent foam dressing each day to draw out moisture from the wound and speed up the closure of the wound

d. Keep the wound dry and stable with a low-toxicity antiseptic, remove only loose slough conservatively, and focus on comfort

Answer: d — For a non-healable wound, wound bed preparation aims for moisture reduction, bacterial control with low-toxicity antiseptics and conservative removal of only loose slough, with goals centred on comfort and stability (section 35.3, Cleansing and Dressings). Option a promotes moisture, which can encourage bacterial overgrowth in a wound that cannot heal. Option b is wrong because only conservative debridement is appropriate for non-healable wounds. Option c expects closure, which is not the goal for a non-healable wound.

Case: Daniel Okafor (Questions 21–26): Daniel Okafor, 46, is brought to the emergency department of a community hospital in northern Ontario 40 minutes after escaping a house fire. He has partial-thickness burns to his face, the front of his chest and both arms, estimated at about 27% of total body surface area. His voice is hoarse, and there is soot around his nostrils and in his mouth. He says he has a headache and feels sick to his stomach. Vital signs: temperature 37.0 °C, heart rate 116, respiratory rate 24, blood pressure 128/78 mm Hg and oxygen saturation 98% on room air. He weighs 80 kg. He rates his pain 9 out of 10 and keeps asking whether his dog got out of the house.

21. [CORE] Which findings should the nurse recognize as cues that need immediate follow-up? Select all that apply.

a. Hoarse voice

b. Soot around his nostrils and in his mouth

c. Headache and nausea after being in a house fire

d. Heart rate of 116 and respiratory rate of 24

e. Pain rated 9 out of 10

f. Temperature of 37.0 °C

g. Asking whether his dog got out of the house

Answer: a, b, c, d, e — A hoarse voice and soot in the nose and mouth after a fire in an enclosed space are cues of inhalation injury, which can make the airway swell and close (a, b; section 35.5). Headache and nausea after smoke exposure are cues of carbon monoxide poisoning (c). A fast heart rate and breathing rate may reflect pain, airway injury, carbon monoxide or early fluid loss and need follow-up (d). Severe pain needs prompt treatment (e). A temperature of 37.0 °C is normal now, although the nurse keeps him warm (f). His worry about his dog matters for emotional support but is not a physical cue that needs immediate follow-up (g).

22. [CORE] Mr. Okafor's oxygen saturation is 98% on room air. Which interpretation is most accurate?

a. The reading rules out carbon monoxide poisoning, because his blood is fully saturated with oxygen right now.

b. The reading may be falsely high if carbon monoxide is present, so a blood carboxyhemoglobin level is needed.

c. The reading shows that his hoarse voice is from shouting for help rather than from an airway injury.

d. The reading means that oxygen can be held until an arterial blood gas shows a low oxygen level.

Answer: b — Pulse oximetry is unreliable in carbon monoxide poisoning because carboxyhemoglobin falsely raises the reading, so it can read normal; a blood carboxyhemoglobin level is measured (b; section 35.5). A normal reading does not rule out carbon monoxide poisoning (a). Oximetry says nothing about the cause of hoarseness, which is a cue of inhalation injury here (c). Oxygen at 15 L/min by non-rebreather mask is started at once after smoke exposure, not held for test results (d).

23. [CORE] Which problem should the nurse treat as the highest priority for Mr. Okafor?

a. Fluid moving out of his blood vessels into the tissues, leading to burn shock

b. Bacteria entering the open burn wounds and spreading through the blood

c. Severe pain and fear that are raising both his heart rate and his breathing rate

d. Swelling of the upper airway from inhalation injury that could block breathing

Answer: d — Airway comes first; a hoarse voice and soot after an enclosed-space fire point to inhalation injury, and swelling can close the airway (d; section 35.5). Burn shock is a real risk and fluid resuscitation is started early, but an obstructed airway would kill sooner (a). Infection is the leading cause of death later in burn care, not in the first hour (b). Pain and fear need treatment, but they do not outrank a threatened airway (c).

24. [CORE] Which plan for Mr. Okafor's first hour best fits his needs?

a. Oxygen at 15 L/min by non-rebreather mask, preparation for early airway management, IV access, small repeated doses of IV analgesia and a call to the burn centre

b. Oxygen at 2 L/min by nasal prongs, ice packs wrapped in towels on the burns, intramuscular morphine for pain and admission to the medical unit for observation

c. Room air until the carboxyhemoglobin result returns, moist dressings on all of the burns, oral analgesia and a referral to plastic surgery as an outpatient next week

d. Oxygen at 15 L/min by non-rebreather mask, cold water poured over all of the burns for 60 minutes, oral analgesia and discharge home once the pain is controlled

Answer: a — High-flow oxygen treats carbon monoxide exposure, the airway may need to be secured early, IV access is needed for fluids, IV analgesia in small doses works reliably, and his burns (partial-thickness burns of 10% TBSA or more and suspected inhalation injury) meet criteria for immediate burn centre consultation (a; section 35.5). Low-flow oxygen, ice and intramuscular opioids are unsafe; intramuscular absorption is unreliable in burns over 10% TBSA (b). Oxygen must not wait for test results, and dressings are not applied before burn team consultation (c). Long cooling of a large burn with cold water risks hypothermia, and he needs transfer, not discharge (d).

25. [RN] The burn centre advises lactated Ringer's at 270 mL/h, a urinary catheter and an adult urine output target of 30 to 50 mL/h. Over the next 2 hours, Mr. Okafor's urine output is 18 mL and then 20 mL. What should the nurse do?

a. Double the IV rate on their own and keep it there until his urine output rises above 50 mL/h.

b. Ask the physician for a diuretic so that his kidneys will make more urine during resuscitation.

c. Report the low output promptly so the team can adjust the fluid rate, and keep measuring hourly.

d. Keep the same rate and recheck in 4 hours, because urine output is often low in the first hours.

Answer: c — The fluid rate is adjusted to urine output by the burn team; output well below 30 mL/h is reported promptly, and hourly measurement continues (c; section 35.5, Going Deeper box). The nurse does not change the ordered rate on their own, and too much fluid causes edema and compartment syndromes (a). A diuretic would not treat low circulating volume and could make it worse (b). Waiting 4 hours with low output risks under-resuscitation and organ failure (d).

26. [CORE] Two hours after arrival, while Mr. Okafor waits for air transfer to the burn centre, which finding shows that his condition is getting worse and needs immediate action?

a. His pain has gone down from 9 to 5 out of 10 after two doses of IV analgesia.

b. He now makes a high-pitched sound when breathing in and is drooling.

c. His urine output for the past hour is 40 mL with the adjusted fluid rate.

d. New thin-walled blisters have formed on the burns on both of his forearms.

Answer: b — Stridor and drooling show that his upper airway is swelling; the nurse calls for help at once so the airway can be secured before transfer (b; section 35.5). Falling pain shows that analgesia is working (a). Urine output of 40 mL/h is within the 30 to 50 mL/h target (c). Blisters are expected in superficial partial-thickness burns (d).

27. [CORE] On day 6 after abdominal surgery, a 64-year-old man coughs and says, "Something just gave way." The nurse finds the incision open, with loops of bowel visible. What should the nurse do first?

a. Gently push the bowel back into the abdomen and close the edges with adhesive strips.

b. Go to the supply room for a suture kit and page the wound care nurse to come and assess him.

c. Stay, call for help, and cover the bowel with sterile gauze moistened with sterile saline.

d. Irrigate the open wound with sterile saline, then cover it with a dry gauze dressing.

Answer: c — Evisceration is a surgical emergency; the nurse stays with the patient, has the surgeon called and covers the organs with sterile saline-moistened gauze (c; section 35.4). Nurses do not try to replace the organs or close the wound (a). Leaving the patient delays help and leaves him alone in an emergency (b). A separated incision is not irrigated without the surgeon, and exposed organs are covered with moist, not dry, gauze (d).

28. [CORE] The nurse assesses a 55-year-old woman's abdominal incision on day 7 after surgery. Which finding is expected?

a. A firm ridge can be felt under the whole length of the incision.

b. Clear yellow fluid is draining from one end of the incision line.

c. The edges of the incision have separated by 1 cm at the centre.

d. The skin around the incision feels warmer than it did on day 3.

Answer: a — A healing ridge of new collagen should be felt along the whole incision between days 5 and 9 (a; section 35.4). Ongoing drainage at this stage is not expected and is reported (b). Separation of the edges is dehiscence (c). Warmth that increases after the first days suggests infection rather than normal inflammation (d).

29. [CORE] A patient with very dark skin is 5 days after a bowel resection. Which approach best helps the nurse find an early surgical site infection?

a. Look for bright redness along the incision under the room's overhead fluorescent light.

b. Ask the patient to call the nurse only if the incision starts to bleed through the dressing.

c. Wait for the white blood cell count result before deciding whether to look at the incision.

d. Feel for warmth and firmness, check swelling and pain, and ask the patient what has changed.

Answer: d — On darker skin, redness may not show, so the nurse relies on warmth, firmness, swelling, pain and the person's own report, compared with nearby skin (d; section 35.4). Looking only for redness misses early infection on darker skin (a). Bleeding is not the main sign of infection, and waiting for it delays detection (b). The nurse assesses the incision directly; a blood test does not replace it (c).

30. [CORE] A 47-year-old man with brown skin is admitted with cellulitis of the left lower leg. Which action best helps the team judge whether the infection is spreading?

a. Wrap the leg firmly from the toes to the knee with an elastic bandage to limit the swelling.

b. Mark the edge of the area and date it, and record how far the warmth and swelling extend.

c. Take one photograph of the leg on admission so the team can compare it at discharge.

d. Keep the leg hanging over the side of the bed to bring more blood flow to the infection.

Answer: b — Marking and dating the edge, and recording warmth and swelling because colour may be hard to see on brown skin, lets the team see spread over time (b; section 35.4). Wrapping the leg does not show whether the infection is spreading and covers the skin the nurse needs to see (a). One photograph cannot show change during the stay (c). The limb is elevated, not kept dependent (d).

31. [CORE] A woman with obesity and long-standing leg edema is recovering from her second episode of leg cellulitis this year. Which teaching is most likely to lower her risk of another episode?

a. Stop taking the antibiotic as soon as the colour of the leg returns to its usual shade.

b. Soak your feet in hot water every evening to keep the skin soft and clean.

c. Check between your toes daily for cracks or moist skin, and manage the swelling.

d. Avoid walking until the swelling in both legs has gone down completely.

Answer: c — Edema and cracked, scaly or moist skin between the toes are risk factors for repeated cellulitis, and treating them lowers the risk (c; section 35.4). Antibiotics are taken as prescribed, not stopped early (a). Daily soaking can leave the skin between the toes moist, which is itself a risk factor (b). Avoiding walking does not treat her risk factors and is not recommended (d).

32. [CORE] A man is going home 3 days after an open hernia repair. Which findings should the nurse teach him to report to his surgeon? Select all that apply.

a. Pain in the incision that is increasing rather than easing

b. Drainage from the incision that is cloudy or smells bad

c. Edges of the incision that are pulling apart

d. A temperature of 38.3 °C

e. A firm ridge felt under the incision during the first week

f. Staples still in place 5 days after surgery

Answer: a, b, c, d — Increasing pain, cloudy or foul-smelling drainage, separating edges and fever are signs of infection or dehiscence and are reported (a, b, c, d; section 35.4, Patient Education box). A healing ridge is a normal sign of healing (e). Staples usually stay in for 7 to 10 days (f).

33. [CORE] A woman calls a telehealth line 5 minutes after spilling boiling water on her forearm. The burn is about the size of her palm. Which advice is best?

a. Hold the forearm under cool running tap water for about 20 minutes and take off any rings or bracelets.

b. Hold a bag of ice wrapped in a thin towel on the forearm for 20 minutes to stop the burning more quickly.

c. Spread butter or cooking oil over the burn to seal out the air, then cover it with plastic wrap.

d. Break any blisters that form with a clean needle, then wrap the forearm in a tight bandage.

Answer: a — Cool or tepid running water for about 20 minutes is the recommended first aid, and jewellery is removed before swelling starts (a; section 35.5). Ice and very cold water are avoided because they can deepen the injury and cause cold injury (b). Butter or oil is not part of recommended first aid, which is cooling with running water (c). Blisters are left for the care team to manage, and a tight wrap can restrict circulation as the tissue swells (d).

34. [CORE] A worker arrives at an emergency department with dry lime powder on both forearms. What should the nurse do first?

a. Pour water over his forearms right away to dilute the chemical as fast as possible.

b. Apply vinegar to the forearms to neutralize the lime before rinsing with water.

c. Cover the forearms with dry sterile dressings and wait for advice from a poison centre.

d. Put on protective equipment, remove his clothing, brush off the powder, then irrigate.

Answer: d — Staff protect themselves, remove contaminated clothing and brush off dry powder before rinsing continuously with water (d; section 35.5). Dry lime is brushed off before any water is applied (a). The recommended first aid is to remove the chemical and rinse with water, not to apply another chemical (b). Waiting without removing the chemical lets the burn deepen; a poison centre can be called while care continues (c).

35. [CORE] During a bed bath, the nurse notices a mole on a 70-year-old man's back. Which finding is most important to report?

a. The mole is round, evenly brown and about 3 mm across.

b. The man says the mole has grown and become itchy in recent months.

c. The man says the mole has looked the same for more than 20 years.

d. Several small, flat, evenly coloured freckles are on both shoulders.

Answer: b — Evolving, a change in size, shape, colour or feel or new itching, is one of the ABCDE warning signs of melanoma (b; section 35.6). A small, round, evenly coloured mole has none of the warning signs (a). A mole that has not changed in years is less concerning (c). Evenly coloured freckles are not warning signs (d).

36. [CORE] A 62-year-old Black man says that a dark streak appeared in his big toenail during the past year and now extends onto the skin next to the nail. What should the nurse do?

a. Explain that dark streaks in the nails are common and harmless in people with darker skin tones.

b. Teach him to apply sunscreen to his feet, because sun exposure causes this kind of change.

c. Report the finding so that he can be assessed promptly for a possible melanoma of the nail.

d. Advise him to keep the toenail trimmed short and to watch the streak for another year.

Answer: c — Acral melanoma is the most common melanoma in people with darker skin and can appear as a dark nail streak extending toward the nail fold; it needs prompt assessment (c; section 35.6). Dismissing the change contributes to late diagnosis (a). Acral melanoma is not linked to sun exposure, so sunscreen would not address it (b). Waiting a year delays diagnosis (d).

37. [CORE] A 74-year-old woman has had a painful band of blisters on the right side of her chest for 1 day. Which statement by the nurse is accurate?

a. "Antiviral medicine works best when started within 72 hours of the rash, so you should be seen today."

b. "Shingles usually spreads to both sides of the chest, so check the left side every day this week."

c. "Antiviral medicine only helps if you start it before the rash appears, so it will not do anything for you now."

d. "Shingles pain always ends when the blisters heal, so you will not need follow-up for pain."

Answer: a — Antivirals are started within 72 hours of rash onset, so same-day assessment matters (a; section 35.6). The rash usually stays on one side and does not cross the midline (b). Antivirals are started after the rash appears, ideally within 72 hours (c). Pain lasting more than 30 days after the rash, postherpetic neuralgia, is the most common complication (d).

38. [CORE] An RPN on a surgical unit is assigned a patient with negative pressure wound therapy on an open abdominal wound. The RPN has never managed this device, and the unit's policy requires education before a nurse cares for it. What should the RPN do?

a. Read the device manual quickly at the bedside, and then change the dressing at the scheduled time.

b. Ask the patient to explain how the dressing was changed and follow those instructions.

c. Turn off the pump until the next shift, when a nurse with education can restart it.

d. Tell the charge nurse about the gap, ask for that task to be reassigned and arrange education.

Answer: d — A nurse performs an activity only with the competence to do it safely, and this unit requires education first; the RPN speaks up and asks for support (d; section 35.6, Scope in Practice box). A quick read does not provide the knowledge, skill and judgment required (a). The patient's description cannot replace education (b). Stopping therapy without an order or assessment could harm the wound (c).

39. [RN] A 70-kg adult has partial-thickness and full-thickness burns covering 30% of total body surface area. The burn team orders lactated Ringer's at 2 mL/kg/%TBSA for the first 24 hours, with the starting hourly rate set at the 24-hour total divided by 16. Which is correct?

a. The 24-hour total is 2,100 mL, and the starting rate is about 131 mL/h.

b. The 24-hour total is 4,200 mL, and the starting rate is about 263 mL/h.

c. The 24-hour total is 4,200 mL, and the starting rate is about 175 mL/h.

d. The 24-hour total is 8,400 mL, and the starting rate is about 525 mL/h.

Answer: b — 2 mL × 70 kg × 30 = 4,200 mL; 4,200 ÷ 16 is about 263 mL/h, which gives half the estimate in the first 8 hours, and the team then adjusts the rate to urine output (b; section 35.5, Going Deeper box). Option a halves the formula (a). Option c spreads the volume evenly over 24 hours (c). Option d uses 4 mL/kg/%TBSA, the older starting point (d).

40. [RN] A 40-year-old man was admitted yesterday with cellulitis of the thigh after a small cut and is receiving IV antibiotics. Which finding most strongly suggests a necrotizing soft tissue infection?

a. The colour change is still inside the edge that was marked and dated on admission.

b. His temperature has come down from 38.4 °C to 37.6 °C since the IV antibiotics were started.

c. He has mild tenderness over the area when the nurse gently presses on the thigh.

d. He has severe pain out of proportion to the skin, with hard tissue past the marked edge.

Answer: d — Pain out of proportion to the visible findings and hard, wooden-feeling tissue beyond the skin change are red flags for necrotizing infection, which needs urgent surgical assessment (d; section 35.4). A change that stays inside the marked edge suggests the infection is not spreading (a). A falling temperature suggests a response to treatment (b). Mild tenderness is expected in cellulitis (c).

36 Eye and Ear Disorders

LEARNING OUTCOMES & COMPETENCY MAPPING

By the end of this chapter, you will be able to:

1. Assess vision and the eyes, and care for adults with vision loss in ways that support safety and independence.
2. Care for adults with cataract, glaucoma, macular degeneration and diabetic retinopathy, including safe use of eye drops.
3. Recognize eye emergencies and give first actions and care after eye surgery, using the CJMM.
4. Assess hearing and recognize types of hearing loss, including hearing loss from ototoxic medicines.
5. Provide communication access for people with hearing loss and Deaf people, and care for hearing aids and cochlear implants in hospital.
6. Care for adults with ear and balance disorders and after ear surgery, including fall prevention.
7. Distinguish RN and RPN roles in eye and ear care using CNO's authority, competence and context.

How the outcomes map to the CNO entry-to-practice competencies

Outcome	RN competency role (CNO, 2019a)	RPN competency category (CNO, 2019b)
1, 2, 3, 4, 6	Clinician; Communicator	Foundations of Practice
5	Advocate; Communicator	Foundations of Practice; Ethical Practice
7	Professional; Collaborator	Legal Practice; Collaborative Practice

Introduction

Sight and hearing link people to everything around them: faces, voices, print, traffic, alarms and the nurse at the bedside. When either sense is impaired, a hospital stay becomes harder and less safe. A person who cannot read a label, find the call bell or hear a question may be judged confused, may fall, or may agree to care they have not understood. Vision loss is common in Canada. Nearly 2.2 million Canadians aged 15 and older (7.4%) reported a seeing disability in 2022 (Statistics Canada, 2025). Much vision loss can be prevented or treated if found early (Fighting Blindness Canada, 2021), and nurses are often first to notice a change.

This chapter is the book's home for eye and ear care. Section 36.1 explains how the eye works, how to assess vision and the eyes, and how to care for people with vision loss. Section 36.2 covers cataract, glaucoma, age-related macular degeneration and diabetic retinopathy. Section 36.3 covers eye emergencies, eye injuries and care after eye surgery. The second half of the chapter turns to hearing and ear assessment (section 36.4), communication access for people with hearing loss and Deaf people, including hearing aids and cochlear implants (section 36.5), and ear and balance disorders and ear surgery (section 36.6).

The chapter builds on earlier ones. Scope of practice for registered nurses (RNs) and registered practical nurses (RPNs) is taught in section 1.3, and the Clinical Judgment Measurement Model (CJMM) in section 1.4. Outside Ontario, practical nurses (PNs) are often called licensed practical nurses (LPNs); this chapter uses "the nurse" unless the roles differ. Disability, accessibility and cultural safety are in Chapter 2, recognizing deterioration and SBAR (Situation, Background, Assessment, Recommendation) in Chapter 6, perioperative care in Chapter 7, and delirium, dementia and falls in Chapter 8. Pupil and cranial nerve assessment are in Chapter 30, stroke and visual field loss in Chapter 31, and diabetes in Chapter 22.

36.1 Vision and Eye Assessment

How the Eye Works

Light enters the eye through the **cornea**, the clear, curved front surface of the eye, which bends incoming light to help focus it. The iris, the coloured part of the eye, controls how much light passes through the pupil. Behind the pupil, the **lens**, a clear structure, works with the cornea to focus light onto the **retina**, the light-sensitive layer at the back of the eye. Photoreceptor cells in the retina turn light into electrical signals, and the **optic nerve** carries these signals to the brain, which turns them into the images we see (National Eye Institute [NEI], 2022). Near the centre of the retina is the **macula**, the area that gives sharp central vision; disease of the macula causes loss of central vision (Eiselen et al., 2026; Figure 36.1).

The front of the eye is filled with a clear fluid called **aqueous humour**. The ciliary processes behind the iris secrete it continuously (Sandoz Canada, 2026). It leaves the eye mainly through a drainage angle at the front of the eye (Royal Victorian Eye and Ear Hospital [RVEEH], 2017) and partly through a second route called uveoscleral outflow (Bausch & Lomb, 2022). The balance between how much fluid is made and how much drains away sets the **intraocular pressure (IOP)**, the pressure inside the eye. Raised IOP is a major risk factor for optic nerve damage and the visual field loss of glaucoma (Sandoz Canada, 2026). A pressure above about 22 mm Hg raises the risk of glaucoma, yet about half of people with glaucoma have normal pressure (Basilious & Buys, 2015). Glaucoma medicines change this balance (Going Deeper box, section 36.3).

Assessing Vision and the Eyes

Assessment starts with the person's own account. The nurse asks:

- **Usual vision:** whether the person wears glasses or contact lenses, uses a magnifier or other aids, and has them in hospital.
- **Change:** whether vision has changed, in one eye or both, and whether the change was sudden or gradual. Sudden change is treated as urgent (section 36.3).
- **Symptoms:** pain, redness, discharge, sensitivity to light, new flashes of light or floaters (section 36.3), halos around lights (section 36.2), and straight lines that look wavy or distorted (Eiselen et al., 2026).
- **History:** eye conditions and every eye drop used, diabetes, high blood pressure, corticosteroid use, family history of glaucoma, and the last eye examination (Basilious & Buys, 2015).

People often do not notice or report gradual vision loss, especially when it develops slowly or occurs with cognitive impairment (US Preventive Services Task Force [USPSTF], 2022). The nurse therefore also watches how the person manages: reading a menu, finding the call bell, recognizing faces and moving around the room.

Visual acuity is the sharpness of vision at a set distance. The most common tools in primary care are standard letter charts such as the Snellen chart; other tools include the pinhole test and the Amsler grid, a square grid of lines used to check central vision (USPSTF, 2022). The nurse follows the setting's procedure for the test and notes whether the person wore their usual glasses or contact lenses (Figure 36.2).

The nurse then inspects the outer eye in good light: eyelids and lashes, the white of the eye, the clarity of the cornea, any discharge, swelling or injury, and whether the eyes look the same. Redness of the white of the eye is visible on every skin tone, but redness of the eyelid skin may show only as a patch darker than the person's usual skin on darkly pigmented skin, so the nurse compares both sides and asks about pain and itching (Chapter 35). Pupil assessment is taught in Chapter 30.

Caring for People With Vision Loss

In 2022, the share of Canadians aged 15 and older with a seeing disability rose with age, from 4.3% at ages 15 to 24 to 11.4% at age 65 and older. It was higher among women+ (8.8%) than men+ (5.9%) (Statistics Canada, 2025). A 2021 report commissioned by Fighting Blindness Canada estimated that 1.2 million people in Canada are living with vision loss and that more than 8 million have one of the four main eye diseases that cause blindness: age-related macular degeneration, glaucoma, diabetic retinopathy and cataract (Fighting Blindness Canada, 2021).

In this chapter, **low vision** means vision loss that cannot be fully corrected with glasses, contact lenses, medicine or surgery and that limits everyday activities. Many people with low vision live independently and know what help they want. The nurse asks rather than assumes and builds care around the person's own methods. Accessibility rights and accommodation are covered in Chapter 2.

- **Introductions:** the nurse says their name and role on entering, speaks directly to the person, and says when they are leaving the room.
- **Orientation:** the nurse describes the surroundings in detail (CNIB, n.d.-b), including the bed controls, call bell, bathroom and the person's belongings, and leaves items where the person put them.
- **Sighted guide: sighted guide** is a way of walking with a person who is blind or partially sighted. The nurse first asks whether the person wants help. If they do, the nurse lightly touches the back of the person's hand with their own hand to signal where the guiding arm is. The person holds the nurse's arm just above the elbow and walks about half a step behind. The nurse describes doors, steps and turns before reaching them and, when leaving, makes sure the person is beside a tangible reference point, such as a wall. The nurse never grabs, pushes or pulls the person, their white cane or their guide dog, and does not pet a guide dog without the owner's permission (CNIB, n.d.-a, n.d.-b).
- **Accessible information:** large print, audio and electronic formats that work with the person's own devices. Among Canadians with a seeing disability who used adaptations, common ones were speech-to-text or text-to-speech, screen magnification and screen readers (Statistics Canada, 2025). Consent forms and discharge teaching are read aloud when needed (Chapter 1).
- **Meals and medications:** the nurse says what is on the tray and where, opens packages if asked, and offers large-print or audio medication information.
- **Safety:** impaired vision is linked with falls and other injuries (USPSTF, 2022). Falls prevention is taught in Chapter 8.

Some people with significant vision loss see images of people, landscapes or patterns that are not there. This is called **Charles Bonnet syndrome**; it follows vision loss from conditions such as macular degeneration and glaucoma, and it is often mistaken for dementia or a mental health problem (Perceptual Neuroscience Laboratory, n.d.). The nurse listens without judgment, reports it and connects the person with vision loss services such as CNIB.

LIFESPAN CONSIDERATIONS

Vision Loss in Older Adults

- **Older adults:** seeing disability is most common at age 65 and older (Statistics Canada, 2025). Cataract, macular degeneration, glaucoma and diabetic retinopathy are the four major blinding eye diseases in Canada (Fighting Blindness Canada, 2021).

- **Hidden loss:** older adults may not notice or report gradual loss, especially when they also have cognitive impairment (USPSTF, 2022). A person who cannot see the clock, the menu or the nurse's face may look disoriented. Vision is checked, and glasses found, before confusion is assumed; delirium and dementia are compared in Chapter 8.
- **Falls:** impaired vision is linked with falls (USPSTF, 2022). Glasses are kept clean, labelled and within reach; the path to the bathroom is lit and clear.
- **Treatment helps:** cataract surgery is associated with fewer falls and lower rates of dementia (Chen et al., 2025). Age alone is never a reason to accept poor vision as normal.
- **Hallucinations:** Charles Bonnet syndrome can be mistaken for dementia (Perceptual Neuroscience Laboratory, n.d.). The nurse asks whether the images are new, whether the person knows they are not real, and reports them so the team can assess.
- **Younger adults:** seeing disability also affects working-age adults; 4.5% of Canadians aged 25 to 44 reported one in 2022 (Statistics Canada, 2025).

36.2 Cataract, Glaucoma and Other Causes of Vision Loss

Cataract

A **cataract** is a clouding of the lens of the eye. Cataract is one of the main causes of impaired vision and blindness. Older age is the main risk factor. Genetics, some medicines such as corticosteroids, eye injury, ultraviolet light exposure, radiation therapy and poorly controlled diabetes also contribute (Chen et al., 2025). Vision becomes gradually blurred or cloudy in one or both eyes. Diagnosis is made by an optometrist or ophthalmologist during an eye examination (Figure 36.3).

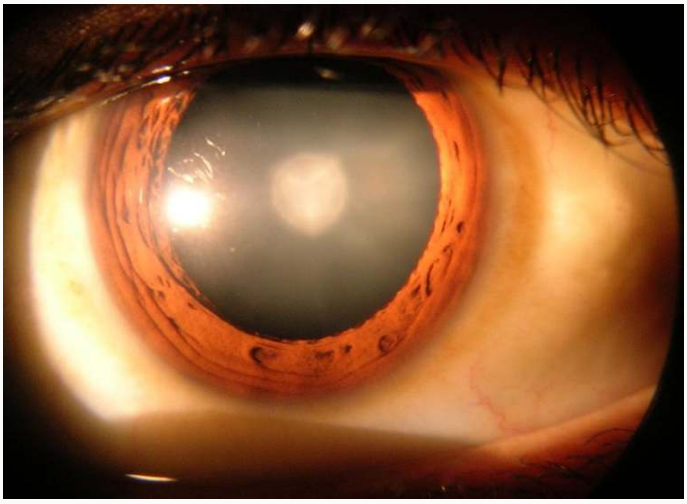

Figure 36.3 Slit-lamp view of a dense cataract clouding the crystalline lens behind the pupil. (credit: “Cataract in human eye” by Rakesh Ahuja, MD/Wikimedia Commons, CC BY-SA 3.0)

Surgery is offered when poor vision interferes with daily activities. The cloudy lens is removed and replaced with a clear artificial lens called an intraocular lens. Antibiotic given inside the eye during surgery has greatly reduced **endophthalmitis**, a sight-threatening infection inside the eye (Chen et al., 2025). Cataract surgery is one of the procedures for which the Canadian Institute for Health Information (CIHI) reports wait times against a benchmark of surgery within 16 weeks (CIHI, 2026). Most people go home the same day (CIUSSS du Nord-de-l'Île-de-Montréal [CIUSSS NIM], 2020); perioperative care is in Chapter 7.

After surgery, teaching follows the surgeon's written instructions. One Canadian hospital network's instructions give a typical plan (CIUSSS NIM, 2020):

- **Shield:** worn at all times on the day of surgery except while drops are given, then at night for the next 7 nights. Nothing is placed between the shield and the eye.
- **Drops:** the prescribed drops are used exactly as ordered, with clean hands, and with 5 minutes between different drops (Figure 36.4).
- **For 2 weeks:** no lifting over about 4.5 kg (10 lb), no bending the head below the shoulders, no rubbing, pressing or squeezing the eye shut, no soap, shampoo, dust or soil in the eye, no gardening, no swimming and no eye makeup.
- **Driving:** not on the day of surgery or for the next few days, and only when the surgeon says it is safe.
- **Warning signs:** unusual or persistent pain, blurred vision, redness or thick greenish discharge need prompt contact with the surgical team or an emergency department.

Figure 36.4 Instilling eye drops: the patient looks up while the nurse gently pulls down the lower lid to form a pocket and holds the dropper tip clear of the eye and eyelashes. (credit: "Instilling eye medication" by British Columbia Institute of Technology (BCIT)/BCcampus, CC BY 4.0)

The nurse treats rising pain or worsening vision after eye surgery as a possible complication, not as expected discomfort, and reports it at once.

Glaucoma

Glaucoma is a group of eye diseases in which the optic nerve is damaged and the visual field shrinks; the loss is progressive, chronic and irreversible (Basilious & Buys, 2015). The two main types are open-angle glaucoma and angle-closure glaucoma.

Open-angle glaucoma develops slowly. It is typically painless and without symptoms until it is advanced, and it may be undiagnosed in about half of the people who have it (Basilious & Buys, 2015). Risk factors include older age, African descent, glaucoma in a parent or sibling, corticosteroid use in or around the eye, myopia (near-sightedness), migraine and raised IOP (Basilious & Buys, 2015). Because the disease is silent, finding it depends on eye examinations. A Canadian Medical Association Journal (CMAJ) article reports that the Canadian Ophthalmological Society (COS) recommends glaucoma screening for people at high risk, and a complete eye examination every 5 years from age 41 to 55, every 3 years from 56 to 65 and every year after 65. People who use corticosteroids (eye drops, injections around the eye or systemic) for more than 2 weeks need a baseline eye examination and regular monitoring (Basilious & Buys, 2015). Public coverage for comprehensive eye examinations varies by province and territory (Fighting Blindness Canada, 2021), so the nurse helps people find out what is covered.

Treatment lowers IOP to slow nerve damage, usually with eye drops (Basilious & Buys, 2015); laser and surgical treatments are also used (Gedde et al., 2026). The main drug classes are named here; how they work is explained in the Going Deeper box in section 36.3.

- **Prostaglandin analogues** such as latanoprost: may permanently darken the iris and change the eyelashes (Bausch & Lomb, 2022).
- **Beta-blockers** such as timolol: see the next paragraph.
- **Carbonic anhydrase inhibitors** such as dorzolamide drops (which may sting and leave a bitter taste) and acetazolamide, given systemically in emergencies (RVEEH, 2017; Sandoz Canada, 2026).
- **Alpha agonists** such as brimonidine: may cause dry mouth and drowsiness, so the person waits until drowsiness or blurring clears before driving (Apotex, 2024).
- **Pilocarpine,** a drop that constricts the pupil, used in acute angle closure (RVEEH, 2017).

Eye drops reach the bloodstream. The Canadian monograph for timolol eye drops warns that it may be absorbed systemically; that cardiac reactions, rarely fatal, and deaths from bronchospasm in people with asthma have been reported; and that it may mask the signs of low blood glucose and of an overactive thyroid. Its contraindications include asthma or a history of asthma, chronic obstructive pulmonary disease (COPD), sinus bradycardia, some forms of heart block, overt heart failure and cardiogenic shock (Sandoz Canada, 2023). Before giving timolol drops, the nurse checks the person's history, heart rate and breathing and reports concerns to the prescriber. Pressing on the inner corner of the eye, or simply closing the eyelid gently, for 2 minutes after each drop reduces systemic absorption (Sandoz Canada, 2023).

Glaucoma drops prevent vision loss but do not restore what is lost, and people feel no different when they skip them. The nurse asks how drops fit the person's day, checks technique, and teaches that stopping drops lets damage continue without warning.

Acute angle-closure glaucoma is an emergency in which the drainage angle closes and IOP rises quickly, usually above 35 mm Hg (RVEEH, 2017). A US guideline from the American Academy of Ophthalmology lists its symptoms as eye pain, headache, nausea or vomiting, and blurred vision with halos around lights (Gedde et al., 2026). The eye may be red, the cornea cloudy and the pupil mid-

dilated and poorly reactive (RVEEH, 2017). Risk factors include older age, female sex, a family history of angle closure, long-sightedness and Inuit or Asian descent (Gedde et al., 2026). In eyes at risk, medicines that dilate the pupil, such as some decongestants, motion sickness medicines and anticholinergic drugs, can trigger an attack (RVEEH, 2017). Treatment lowers IOP promptly, usually with medicines, and is followed by a procedure such as laser peripheral iridotomy; the other eye usually needs prompt treatment too (Gedde et al., 2026). The nurse notifies the prescriber at once, gives ordered medicines and antiemetics, and checks that kidney function has been reviewed before acetazolamide (RVEEH, 2017; Chapter 27; Figure 36.5).

CLINICAL JUDGMENT

Sudden Eye Pain and Halos

Names and details are fictional; this is a composite story.

Mr. Anton Petrakis, 71, is on a medical unit on day 2 of treatment for a urinary tract infection. Early in the evening he calls the nurse, holding his left hand over his left eye.

- **Recognize cues:** severe aching pain in the left eye and brow, a headache, blurred vision with "rainbow rings" around the ceiling lights, and two episodes of vomiting. The left eye is red and the pupil is larger than the right and reacts sluggishly. That afternoon he received an anticholinergic medicine for bladder spasm.
- **Analyze cues:** sudden pain, halos, vomiting and a mid-dilated pupil fit acute angle-closure glaucoma. A pupil-dilating medicine may have triggered it (RVEEH, 2017).
- **Prioritize hypotheses:** acute angle closure is the most urgent problem because vision can be lost; stroke and raised intracranial pressure are also considered because of the headache and unequal pupils (Chapters 30 and 31). His speech, limb strength and level of consciousness are unchanged.
- **Generate solutions:** urgent assessment, ordered pressure-lowering medicines, an antiemetic and analgesia; hold further doses of the anticholinergic until reviewed.
- **Take action:** the nurse completes a neurologic check, which is otherwise unchanged, and calls the most responsible provider using SBAR (Chapter 6): "I am concerned about acute angle-closure glaucoma." Ophthalmology is called urgently. The RN gives the ordered drops and medicines and checks his kidney function results.
- **Evaluate outcomes:** pain, nausea and vision are reassessed; the ophthalmologist measures his IOP and plans laser treatment, likely for both eyes (Gedde et al., 2026). The nurse documents the timeline, flags the anticholinergic for review and explains to Mr. Petrakis why his other eye needs checking too.

PATIENT EDUCATION

Using Eye Drops

- Wash your hands. Shake the bottle if told to (CIUSSS NIM, 2020).
- Tilt your head back, look up and pull down the lower eyelid to make a pocket.
- Let one drop fall into the pocket without touching your eye, eyelid or lashes with the tip of the bottle (Nova Scotia Health, 2026).
- Close your eye gently. Press a finger on the inner corner of the eye, beside the nose, for 2 minutes. This keeps more of the medicine in the eye and less in the bloodstream (Sandoz Canada, 2026). Blot extra liquid; do not rub.
- If you use more than one kind of drop, wait between them. Your pharmacist will tell you how long; monographs for different drops say at least 5 or at least 10 minutes (Bausch & Lomb, 2022; Sandoz Canada, 2023).

- Remove contact lenses before drops and wait at least 15 minutes before putting them back in (Bausch & Lomb, 2022).
- Store each bottle as the label says. Some bottles are kept in the refrigerator before opening (Bausch & Lomb, 2022).
- Do not stop drops for your other eye unless your eye doctor tells you to (Nova Scotia Health, 2026).
- Tell your health care team if drops make you dizzy, short of breath or very tired.

Macular Degeneration and Diabetic Retinopathy

Age-related macular degeneration (AMD) damages the macula and causes loss of central vision. Early and intermediate AMD are marked by drusen, yellow deposits beneath the retina, and may cause few symptoms or trouble seeing in dim light. Late AMD takes two forms that often occur together. In dry AMD, retinal cells waste away slowly. In wet AMD, abnormal blood vessels grow under the retina and leak fluid or blood. Straight lines may look wavy, and a blurred or missing patch may appear in the centre of vision. Age is the strongest risk factor; smoking is the main one a person can change, and a family history of AMD roughly triples the risk (Eiselen et al., 2026; Figure 36.6).

Figure 36.6 Retinal fundus photograph showing clustered yellow drusen in the macula in age-related macular degeneration. (credit: "MacularDegenerationFundus" by Tmhlee/Wikimedia Commons, CC BY-SA 3.0)

People with AMD may be asked to check each eye with an Amsler grid regularly. Any new distortion or central blur needs review by an eye specialist within 24 hours. Wet AMD is treated with **anti-VEGF therapy**, medicines that block vascular endothelial growth factor, given by injection into the eye. Examples include ranibizumab, aflibercept and faricimab. Treatment continues over the long term, and many people stop or miss treatment; studies have found that 17.5% to 30% of patients do not keep to it (Eiselen et al., 2026). The nurse supports transportation and appointments and offers low-vision services such as CNIB.

Diabetic retinopathy is damage to the retina caused by diabetes. Good glucose control lowers the risk that it starts or worsens. Diabetes Canada recommends screening by an optometrist or ophthalmologist, either at an in-person examination or by reading retinal photographs taken after the pupils are dilated. Adults with type 1 diabetes are screened every year, starting 5 years after diabetes begins. Adults with type 2 diabetes are screened at diagnosis, then every 1 to 2 years if no or minimal retinopathy is found. Results are shared with the whole diabetes care team. Treatment includes anti-VEGF injections and laser (Altomare et al., 2018). Diabetes care and its screening programs are taught in Chapter 22.

Higher rates of diabetic retinopathy have been reported in Indigenous populations in Canada (Altomare et al., 2018). Diabetes Canada's chapter on type 2 diabetes and Indigenous peoples names colonization, including residential schools and forced relocation, along with poverty, food insecurity, racism and inequities in health services, as drivers of the higher burden of type 2 diabetes (Crowshoe et al., 2018). Many First Nations, Inuit and Métis people live in rural, remote or northern communities where specialist eye care may be hard to reach or absent. On Vancouver Island, a First Nations teleophthalmology service brought retinal photography to communities with First Nations technicians and an eye care nurse. During the 1-year project, clinics were held in 43 of 51 communities and 524 people were screened. Data were stored at a First Nations-operated facility, following the First Nations principles of ownership, control, access and possession (OCAP®) (Kim & Driver, 2015). Services designed with communities, close to home, are one way to close these gaps. The main causes of vision loss in this section are compared below (Table 36.1).

Table 36.1 Common causes of vision loss in adults compared (Altomare et al., 2018; Basilious & Buys, 2015; Chen et al., 2025; Eiselen et al., 2026; Gedde et al., 2026)

Condition	What changes	How vision is affected	Key nursing points

Condition	What changes	How vision is affected	Key nursing points
Cataract	The lens becomes cloudy, mostly with age	Gradual blurring or clouding; reversible with surgery	Teach shield, drops and activity limits after surgery; report rising pain or worsening vision
Open-angle glaucoma	Slow optic nerve damage, often with raised IOP	No symptoms until late; visual field loss that cannot be restored	Encourage eye examinations for people at risk; support lifelong drop use; watch for systemic effects of drops
Acute angle-closure glaucoma	The drainage angle closes and IOP rises quickly	Sudden blurring with halos, eye pain, headache, nausea and vomiting	Treat as an emergency; notify at once; give ordered medicines and antiemetics
Age-related macular degeneration	Deposits and cell loss in the macula; in the wet form, leaking new vessels	Central blur or distortion; side vision usually kept	Teach Amsler grid checks; urgent review of new distortion; support injection visits and low-vision services
Diabetic retinopathy	Diabetes damages the retina	May have no symptoms until advanced	Promote screening on schedule; support glucose control; share results with the team

36.3 Eye Emergencies, Trauma and Eye Surgery

Eye Emergencies

Sudden vision loss, a chemical in the eye, a penetrating injury and new flashes with a shadow over vision are emergencies. Every nurse who notices one acts at once and escalates (College of Nurses of Ontario [CNO], 2025): the RPN consults the RN as the patient's needs change, and the most responsible provider is notified using SBAR (Chapter 6). Common emergencies and first actions are compared below (Table 36.2).

- **Chemical injury:** a chemical splash is irrigated at once, before anything else, and irrigation continues while help is called. Workplace safety guidance calls for flushing to start within 10 seconds and continue for at least 15 minutes with the eyelids held open (WorkSafeNB, 2024). In hospital, normal saline or lactated Ringer's solution is used, or water if nothing else is at hand, through an irrigation lens or intravenous tubing. At least 2 L are given; the pH of the eye surface is rechecked about 5 minutes after starting, and irrigation continues until it is 7.0 to 7.5. Alkali burns are generally more harmful than acid burns because alkali penetrates the surface of the eye faster. Ophthalmology sees the person as soon as the eye is neutralized (Gelston & Deitz, 2020). The nurse records the time irrigation began, the fluid and volume used, and each pH result.

Figure 36.7 Prominent hyphema filling the anterior chamber in front of the iris, with surrounding ciliary injection. (credit: “12886 2014 Article 436 Fig1 HTML” by Yoko Okunuki et al./BMC Ophthalmology, CC BY 4.0)

- **Penetrating injury and foreign objects:** a rigid metal shield is placed over the eye without pressing on it. An object sticking out of the eye is never removed. The person avoids coughing and straining, receives an antiemetic so they do not vomit, and has tetanus status checked. Urgent ophthalmology is needed, because surgery within 24 hours lowers the risk of infection inside the eye (Gelston & Deitz, 2020).
- **Blunt trauma and hyphema:** a blow to the eye can cause bleeding inside the front of the eye, seen as blood in front of the iris; this is called **hyphema**. The sources list hyphema as a possible sign of a serious injury to the eyeball and as a reason for referral (Gelston & Deitz, 2020; Wipperman & Dorsch, 2013; Figure 36.7).

- **Corneal abrasion:** a **corneal abrasion** is a scratch in the outer layer of the cornea from injury, a foreign body or contact lens wear. It causes pain, tearing, light sensitivity and a feeling that something is in the eye. Patching is not recommended, and numbing drops are not given for home use because they delay healing and mask worsening. Contact lens wearers stop wearing lenses until healed. Most abrasions heal in 24 to 48 hours; worsening pain, loss of vision or no improvement within 24 hours needs referral (Wipperman & Dorsch, 2013).
- **Retinal detachment:** in **retinal detachment**, the retina separates from the back of the eye. Warning signs are sudden flashes of light and new floaters in one eye, with a shadow or patch of lost vision that may spread. People with these symptoms need assessment within 24 hours (Gelston & Deitz, 2020).
- **Sudden painless vision loss:** sudden loss of vision without pain may mean a blocked artery to the retina. It needs immediate ophthalmology referral and assessment for stroke (Chapter 31). In people over 50, especially with jaw or scalp tenderness, fever, fatigue or weight loss, giant cell arteritis is considered (Gelston & Deitz, 2020; Chapter 34).

Table 36.2 Eye emergencies and first nursing actions (based on Gelston & Deitz, 2020; Gedde et al., 2026; Wipperman & Dorsch, 2013; WorkSafeNB, 2024)

Emergency	Signs	First actions	Do not
Chemical injury	Splash of a chemical; pain, redness, tearing, blurred vision	Irrigate at once and keep going while help is called; check pH as ordered; urgent ophthalmology	Delay irrigation to identify the chemical or find a provider
Penetrating injury or embedded object	Injury by a sharp or high-speed object; object may be visible; vision loss	Place a rigid shield without pressure; give ordered antiemetic; urgent ophthalmology	Press on the eye, patch it tightly or remove the object
Hyphema after blunt trauma	Blood in the front of the eye after a blow; pain; blurred vision	Protect the eye; report promptly for referral	Assume a black eye is minor without checking vision
Corneal abrasion	Pain, tearing, light sensitivity, foreign body feeling	Check vision; report; teach ordered treatment and when to return	Patch the eye or send the person home with numbing drops
Retinal detachment	Sudden flashes, new floaters, spreading shadow over vision	Report the same day for assessment within 24 hours	Reassure the person that floaters are always harmless
Acute angle-closure glaucoma	Eye pain, headache, halos, nausea and vomiting, red eye	Notify at once; give ordered pressure-lowering medicines and antiemetic	Give pupil-dilating medicines or wait to see if it settles
Sudden painless vision loss	Loss of all or part of vision in one eye	Escalate immediately; consider stroke and giant cell arteritis	Wait until morning or treat it as a non-urgent referral

Care After Eye Surgery

Cataract surgery is usually day surgery (section 36.2), and after other eye operations, too, much of the recovery happens at home. Nursing care protects the eye, controls pain and nausea, prevents falls and prepares the person to manage alone.

- **Protecting the eye:** no pressure on the eye, no rubbing, and a shield at night for about the first week as the surgeon directs; a cloth eye pad or patch is not used (Nova Scotia Health, 2026).
- **Pain and nausea:** pain that is not relieved by acetaminophen or ibuprofen, worsening vision, marked swelling, or nausea and vomiting that do not settle are reported to the surgeon right away (Nova Scotia Health, 2026).
- **Falls:** with one eye shielded or blurred, the person is at higher risk of falls. The nurse keeps the call bell and glasses within reach, asks the person to call before getting up the first time, and applies the falls prevention plan in Chapter 8.

After surgery for retinal detachment, the surgeon may place a bubble of gas inside the eye to hold the retina in place. The person's position matters. They lie face down or on one side exactly as the surgeon directs and must not lie flat on their back, which can cause serious complications (Nova Scotia Health, 2026). Incorrect positioning can make the surgery fail (Alcon, 2022). Vision in the eye is blurred while the bubble is present, and as it shrinks, its edge may look like a dark line at the top of the person's vision (Nova Scotia Health, 2026).

Until the bubble is gone, the person must not travel by air or drive through high-altitude areas, because the gas expands at altitude and can cause eye pain and pressure (Nova Scotia Health, 2026). US labelling for one gas product adds that a rise in eye pressure from a change in elevation can result in blindness, and that the person must not receive nitrous oxide, sometimes used in anesthesia, until the gas has dissolved, because it can also raise the pressure in the eye and cause blindness (Alcon, 2022). The person wears a gas bubble wristband and carries a card until the gas is gone, and tells any surgeon or anesthetist about the bubble before another procedure (Alcon, 2022; Nova Scotia Health, 2026). The nurse checks for this wristband during admission and before any anesthetic, and includes it in every handover (Chapter 7). How long the gas lasts depends on the gas used; one product's labelling gives about 6 to 8 weeks (Alcon, 2022), so the person follows their surgeon's time frame.

Before discharge, the nurse confirms who will drive the person home and that they will not drive until the surgeon allows (Nova Scotia Health, 2026). Activity limits after retinal surgery last longer than after cataract surgery: one Canadian program advises avoiding dirt, dust and chemicals, lifting more than about 4.5 kg, heavy exercise, sports and swimming for the first 4 weeks (Nova Scotia Health, 2026). People who use glaucoma drops keep using drops in the other eye unless told otherwise. The nurse reviews eye drop technique, activity limits and warning signs, and checks that the person can manage positioning, meals and medications at home or has help arranged.

GOING DEEPER

Intraocular Pressure and How Glaucoma Medicines Work

Required for RN students; optional for PN students.

IOP reflects a balance between aqueous humour made by the ciliary processes and aqueous humour leaving the eye through the drainage angle and the uveoscleral route. Each class of glaucoma medicine acts on one side of that balance or both.

- **Less fluid made:** beta-blockers such as timolol and carbonic anhydrase inhibitors such as dorzolamide reduce aqueous humour secretion. Combining them lowers IOP more than either alone (Sandoz Canada, 2026).
- **More fluid out:** prostaglandin analogues such as latanoprost increase outflow, mainly by the uveoscleral route (Bausch & Lomb, 2022).
- **Both:** brimonidine, an alpha agonist, reduces production and increases uveoscleral outflow (Apotex, 2024).
- **In acute angle closure,** pressure must fall quickly, so several medicines are given together: a carbonic anhydrase inhibitor such as acetazolamide given systemically, pilocarpine and other pressure-lowering drops. Kidney function is checked before acetazolamide (RVEEH, 2017). Laser peripheral iridotomy then gives fluid a new path (Gedde et al., 2026).

Systemic effects follow from drug class: a beta-blocker drop can slow the heart or tighten the airways (Sandoz Canada, 2023); dorzolamide is a sulfonamide, and serious skin reactions have been reported (Sandoz Canada, 2026); brimonidine adds to the effect of sedatives and must not be used with monoamine oxidase (MAO) inhibitors (Apotex, 2024). **Punctal occlusion,** pressing on the inner corner of the eye after a drop, reduces how much drug reaches the bloodstream (Sandoz Canada, 2023).

36.4 Hearing and Ear Assessment

Hearing loss is one of the most common conditions the nurse meets in adult care, and one of the easiest to miss. A person who cannot hear the questions may give answers that do not fit, agree to things they did not understand or seem withdrawn. This section reviews how the ear works, the main types and causes of hearing loss in adults, including loss caused by medicines, and how the nurse assesses hearing. Testing of the cranial nerves is covered in Chapter 30.

How the Ear Works

The ear has three parts. The **outer ear** is the visible ear and the ear canal, which ends at the **tympanic membrane** (eardrum). Glands in the outer third of the canal make **cerumen** (earwax), which protects and lubricates the canal and slowly moves outward on its own as the jaw moves (American Academy of Otolaryngology–Head and Neck Surgery Foundation [AAO-HNSF], 2018a). Sound travels down the canal and makes the eardrum vibrate (Figure 36.8).

The **middle ear** is a small air-filled space behind the eardrum. Its three tiny bones, the malleus, incus and stapes, pass the vibrations along and make them stronger. The **inner ear** holds the **cochlea**, a fluid-filled, snail-shaped organ lined with hair cells. Movement of the fluid bends the hair cells, which turn the vibration into an electrical signal. Hair cells at one end of the cochlea respond to high-

pitched sounds and those farther along respond to lower ones. The auditory nerve carries the signal to the brain, which hears it as sound (National Institute on Deafness and Other Communication Disorders [NIDCD], 2022).

The inner ear also senses balance. Its vestibular organs, including the semicircular canals, detect movement of the head and its position relative to gravity (Bhattacharyya et al., 2017; NIDCD, 2022). This is why some inner ear disorders cause both hearing loss and dizziness (section 36.6).

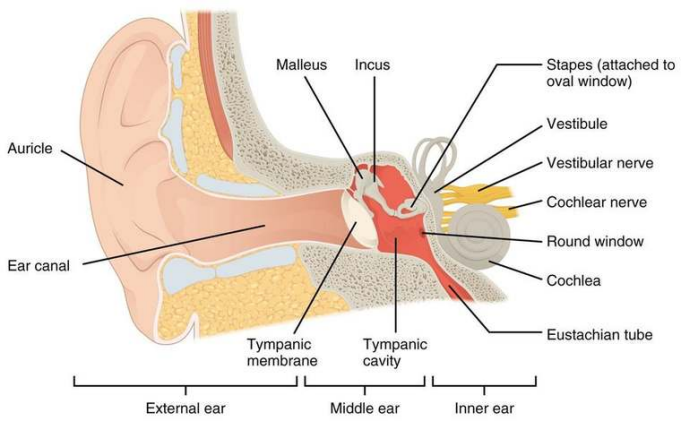

Figure 36.8 Anatomy of the human ear showing the external ear, the air-filled middle ear containing the auditory ossicles (malleus, incus, stapes) and tympanic membrane, and the fluid-filled inner ear (cochlea and vestibular apparatus). (credit: "Figure 14.5, Ear Structures" by J. Gordon Betts et al./OpenStax, Anatomy and Physiology 2e, CC BY-NC-SA 4.0)

Hearing Loss in Adults

Hearing loss is grouped by where the problem lies (Table 36.3). **Conductive hearing loss** occurs when sound cannot get through the outer or middle ear to a normal inner ear, for example because of impacted wax, fluid or a damaged eardrum. It may be temporary or permanent and can often be treated. **Sensorineural hearing loss** comes from damage to the cochlea or the hearing nerve and is usually permanent. **Mixed hearing loss** combines the two (University Hospitals Sussex NHS Foundation Trust, 2026; World Health Organization [WHO], 2026).

The most common pattern in older adults is **presbycusis**, age-related sensorineural hearing loss. It starts at the highest pitches and later spreads to lower ones. Consonants become hard to hear, so speech sounds mumbled, and conversation in a noisy or echoing room becomes difficult (Feder et al., 2015). Loud noise is another preventable cause (WHO, 2026). A Statistics Canada survey analysis found more hearing loss in men than in women and linked the gap partly to noise at work and in leisure (Feder et al., 2015).

Ototoxicity is damage to the inner ear, affecting hearing, balance or both, caused by a medicine or chemical. Aminoglycoside antibiotics such as gentamicin are a key example. The Canadian monograph warns that they can damage the eighth cranial nerve, mostly with high blood levels and poor kidney function. Early signs are **tinnitus** (ringing or roaring in the ears) and loss of high-pitched hearing, which may show only on a hearing test; balance damage causes nausea, vomiting, dizziness, **vertigo** (a false sense of movement) and an unsteady gait. Hearing loss can be permanent and may appear after treatment ends. Older age, dehydration, kidney disease, long courses and loop diuretics such as furosemide add to the risk. The monograph calls for peak and trough drug levels, kidney function tests and an audiology referral if tinnitus or hearing loss is reported (Baxter Corporation, 2019). The cancer drug cisplatin can cause cumulative, high-pitched hearing loss and tinnitus, and its monograph calls for a hearing test before treatment and before each dose (Accord Healthcare, 2024). Acetylsalicylic acid (ASA) in excess can cause tinnitus and vertigo (Pharmascience, 2018). Kidney function and drug clearance are covered in Chapter 27.

Hearing loss is common in Canada. In the Canadian Health Measures Survey (2012 to 2015), about 38% of adults aged 20 to 79 had hearing loss measured by audiometry, rising from 9% at ages 20 to 39 to 94% at ages 70 to 79 (Statistics Canada, 2021). Among adults aged 40 to 79, about 54% had high-frequency hearing loss that was at least mild, yet only about 6% had a self-reported hearing impairment, and about 77% of those with measured loss did not perceive it (Ramage-Morin et al., 2019). Hearing loss is linked to social isolation, depression, falls, cognitive decline and dementia (Ramage-Morin et al., 2019). Hearing impairment also raises the risk of delirium in hospital (Chapter 8, section 8.2).

Assessing Hearing

Because most hearing loss goes unnoticed, the nurse asks every adult directly rather than waiting to be told. Useful questions are: Do you have trouble hearing? Do you use hearing aids or a cochlear implant, and are they with you? Which ear is better? Do you lip-read or use sign language? How do you prefer to communicate? The history also covers whether the change was sudden or gradual, one ear or both, tinnitus, dizziness, ear pain, discharge or fullness, noise exposure and current medicines. A sudden loss in one ear is urgent (section 36.6).

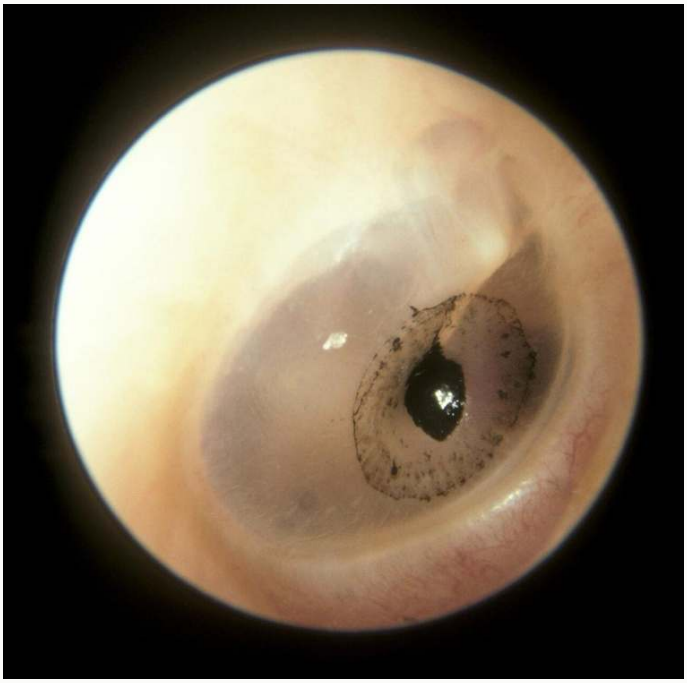

Figure 36.9 Otoscopic view of a right tympanic membrane showing the translucent pearly grey eardrum and landmarks (the small black dot is India ink placed to demonstrate normal outward migration of the canal epithelium). (credit: "Ink Dot on the surface of the tympanic membrane 1 week later" by Michael Hawke, MD/Wikimedia Commons, CC BY 4.0)

The **whispered voice test** is a quick bedside screen. In the method described in a systematic review, the examiner stands about an arm's length behind the seated person so they cannot lip-read, masks the other ear by closing it gently with a finger and rubbing in a small circle, breathes out quietly and then whispers a mix of numbers and letters for the person to repeat. Each ear is tested separately. In adults the test was simple and accurate, but results depend on doing it the same way each time (Pirozzo et al., 2003). A failed screen leads to referral, not a diagnosis.

With an otoscope, the nurse who has the competence looks at the canal and eardrum for wax, redness, swelling or discharge. **Cerumen impaction** is a build-up of wax that blocks the canal or causes symptoms such as fullness, muffled hearing, tinnitus, itching or ear pain (AAO-HNSF, 2018a). In the Canadian survey, wax or pus blocked the ear canal in 13% of adults, rising to 21% at ages 70 to 79 (Feder et al., 2015). Cotton swabs push wax deeper and can injure the eardrum, and hearing aid users are advised to have their ears checked every 6 to 12 months (AAO-HNSF, 2018a). Removing wax is covered in section 36.6 (Figure 36.9).

People with suspected hearing loss are referred to an audiologist, who measures hearing with a pure-tone test and records it on an **audiogram**.

Table 36.3 Types of hearing loss compared (Feder et al., 2015; Milchard, n.d.; University Hospitals Sussex NHS Foundation Trust, 2026; WHO, 2026)

Type	Where the problem is	Common causes	What helps
Conductive	Outer ear or middle ear; sound cannot reach an inner ear that works normally	Impacted earwax, a swollen ear canal from infection, fluid or infection in the middle ear, a hole in the eardrum, a middle ear bone that cannot move	Treating the cause, such as wax removal, treating infection or surgery; hearing aids
Sensorineural	Inner ear (cochlea) or the hearing nerve	Aging, loud noise, ototoxic medicines, sudden sensorineural hearing loss, Ménière disease	Usually permanent; hearing aids, cochlear implants for severe loss, communication strategies; urgent assessment if the loss is sudden
Mixed	Both the outer or middle ear and the inner ear	For example, age-related loss plus impacted wax	Treating the conductive part and supporting hearing for the rest

GOING DEEPER

Reading an Audiogram

Required for RN students; optional for PN students.

An audiogram charts the softest sounds a person can hear in each ear. Pitch, in hertz (Hz), runs across the top from low (left) to high (right); testing usually covers 250 to 8,000 Hz. Loudness, in decibels hearing level (dB HL), runs down the side, softest at the top. The lower the marks fall, the greater the loss (Milchard, n.d.; University Hospitals Sussex NHS Foundation Trust, 2026).

- **Air conduction:** sounds through headphones, marked O for the right ear and X for the left; they show how the whole ear hears.
- **Bone conduction:** sounds sent by a small vibrator behind the ear straight to the inner ear, bypassing the outer and middle ear.

- **Air–bone gap:** when bone conduction is clearly better than air conduction in the same ear, the problem lies in the outer or middle ear (conductive loss). When bone conduction thresholds are also above 20 dB HL and there is no real gap, the loss is sensorineural; when bone conduction is above 20 dB HL and a gap remains, it is mixed (Milchard, n.d.).
- **Degree:** one hospital audiology service describes thresholds of up to 20 dB as within normal limits, 20 to 40 dB as mild, 40 to 70 dB as moderate, 70 to 95 dB as severe and above 95 dB as profound (University Hospitals Sussex NHS Foundation Trust, 2026). Cut-offs differ slightly between organizations.

Age-related loss usually slopes downward toward the right side of the chart, because high pitches go first (Feder et al., 2015).

36.5 Communication Access, Hearing Aids and Cochlear Implants

Communication access means a person can understand and be understood in the way that works for them. Without it, consent is not truly informed, teaching does not land and a person who cannot hear may be wrongly labelled confused. Consent and capacity are covered in Chapter 1, and disability and accessibility in Chapter 2. This section applies those principles to people who are hard of hearing, deafened or Deaf.

Communicating With People Who Have Hearing Loss

The nurse starts by asking how the person communicates best and records it in the health record so the whole team uses it (Arora et al., 2026; Southlake Regional Health Centre, n.d.). Simple habits then make a large difference (Banks, 2020; Southlake Regional Health Centre, n.d.):

- Get the person's attention before speaking, face them and keep the face in full view.
- Talk in a well-lit place so the face is easy to see.
- Turn off the television, close the door or move to a quieter spot.
- Speak a little louder and a little slower, as clearly as possible.
- Check understanding by asking the person to say the plan back; if they have not understood, rephrase, write it down or use a speech-to-text app.
- Answer call bells in person, and explain any emergency face to face.

Lip-reading helps but has limits. Only about 30% to 40% of spoken English can be seen on the lips (Steinberg et al., 2006). Writing helps many hard-of-hearing people, but it is not a substitute for an interpreter for a Deaf person whose first language is a signed language, since American Sign Language has no written form and English may be a second language (Steinberg et al., 2006).

A **personal amplifier**, a small handheld device that makes nearby speech louder through headphones or earphones, can make bedside conversation easier when hearing aids are not available. In a Toronto hospital, staff reported that amplifiers made conversations easier and clearer, reduced the need to raise their voices and helped older patients take part in decisions, including discussions of capacity. The same study noted that at least two in three older adults in hospital have hearing loss, yet patients often do not mention it, and staff often had trouble finding the devices on the unit (Arora et al., 2026).

Masks add another barrier. They muffle sound, especially high pitches, and hide the lips and facial expressions; for Deaf signers they also hide facial grammar. Masks with a clear window let a person see the lips but muffle sound the most, and a face shield over a mask adds more distortion (Banks, 2020). The nurse follows infection prevention and control requirements (Chapter 4) and adds the other supports above. Mask loops can also pull off hearing aids or cochlear implant processors, so devices are checked after a mask is removed (Banks, 2020).

Deaf People and Sign Language Interpreters

Words matter to this community. **Deaf** with a capital D describes people who share Deaf culture and use a signed language as their main language; it is a cultural identity, not a hearing level. Lowercase "deaf" describes severe hearing loss, "hard of hearing" covers mild to severe loss in people who often use speech, and "deafened" describes people who lost their hearing, usually as adults. "Hearing impaired" is best avoided, and the nurse uses the terms people choose for themselves (Sexton, 2022). Many Deaf people do not see themselves as disabled but as members of a language and cultural group (Sexton, 2022).

American Sign Language (ASL) and **langue des signes québécoise (LSQ)** are full languages with their own grammar. The federal *Accessible Canada Act* recognizes ASL, LSQ (called Quebec Sign Language in the Act) and Indigenous sign languages as the primary languages of communication for deaf persons in Canada (*Accessible Canada Act*, 2019). That Act applies to federally regulated bodies; hospitals are governed mainly by provincial and territorial laws.

A Deaf patient who signs needs a qualified sign language interpreter for assessments, consent discussions, teaching and discharge planning. In Ontario, hospitals book interpreters through their own process; one hospital's policy uses a central scheduling service with interpreters available around the clock for emergencies, and groups teaching and assessments into each booking (Southlake Regional Health Centre, n.d.). **Video remote interpreting (VRI)** brings an interpreter into the room on a screen. It depends on a connection good enough to show fingerspelling clearly (Steinberg et al., 2006).

Family members should not interpret. In a study of Deaf adults, family members were often inadequate go-betweens, patients felt left out of their own care and privacy was lost (Steinberg et al., 2006). A qualified interpreter is impartial and does not edit what is said (Southlake Regional Health Centre, n.d.). If an interpreter is not yet available in an urgent situation, the nurse uses the best interim method, such as a staff member who signs or writing, and keeps trying to reach an interpreter (Southlake Regional Health Centre, n.d.). Interpreters are part of care, not visitors, and the nurse keeps a signer's hands free whenever possible. Each interpreter session is documented with the interpreter's name, date and time (Southlake Regional Health Centre, n.d.).

Figure 36.10 An external behind-the-ear cochlear implant sound processor and its round magnetic transmitting headpiece, which sits over the internal receiver under the scalp. (credit: “Advanced Bionics cochlear implant processor BTE (first-generation behind-the-ear processor)” by MikeCore9918/Wikimedia Commons, CC BY-SA 4.0)

These duties have a legal basis. In 1997 the Supreme Court of Canada ruled that when sign language interpretation is needed for effective communication in health care, not providing it breaches the equality rights of Deaf people under section 15 of the *Canadian Charter of Rights and Freedoms* (*Eldridge v. British Columbia (Attorney General)*, 1997). In Ontario, the customer service requirements under the *Accessibility for Ontarians with Disabilities Act, 2005* (AODA) and its Integrated Accessibility Standards expect organizations to communicate in a way that takes a person's disability into account, and to provide accessible formats and communication supports when asked, promptly and at no extra cost (Government of Ontario, 2026).

Hearing Aids and Cochlear Implants in Hospital

A **hearing aid** is a small electronic device worn in or behind the ear that makes sound louder. A **cochlear implant** is an electronic device for people who are severely hard of hearing or profoundly deaf. An external sound processor worn behind the ear works with a part placed under the skin by surgery; together they work around the damaged inner ear and send signals straight to the hearing nerve. It does not restore normal hearing (NIDCD, 2024; Figure 36.11; Figure 36.10).

At admission, the nurse asks about devices and whether they came to hospital. Patients often leave hearing aids at home, partly because they fear losing them (Arora et al., 2026), so the nurse asks family to bring them when needed. The nurse records the devices, which ears they are for and how the person uses them. Hearing aids and processors are worn during waking hours and always for assessments, teaching and consent discussions. The nurse checks that batteries are charged or replaced, follows the person's routine for cleaning, and stores devices that are out in a labelled container kept in the same place each time; one Ontario

Figure 36.11 A behind-the-ear hearing aid with tubing leading to an earmold in the ear canal. (credit: “Behind-the-Ear Hearing Aid grayscale photo” by Steve Johnson/Wikimedia Commons, CC BY 2.0)

hospital's hearing toolkit includes a cup for devices and storage instructions (Southlake Regional Health Centre, n.d.). Devices are named in handover and on transfers.

Cochlear implants contain a magnet, which matters for magnetic resonance imaging (MRI). Many implants are labelled "MR Conditional", meaning a scan is possible only under the manufacturer's specific conditions. Some newer magnets can rotate in place; others need a splint or bandage kit made for that implant, or surgical removal of the magnet before the scan. Risks include movement of the magnet with pain or injury, and heating (U.S. Food and Drug Administration [FDA], 2021). The nurse makes sure the MRI team knows about the implant, asks for the person's implant card with the brand and model, and leaves the decisions to the MRI team following the manufacturer's instructions (FDA, 2021).

CANADIAN CONTEXT

Deaf, deaf and Hard of Hearing People in Canada

Canada recognizes signed languages in law. The *Accessible Canada Act* (2019) names American Sign Language, Quebec Sign Language and Indigenous sign languages as the primary languages of communication for deaf persons in Canada. In *Eldridge* (1997), the Supreme Court of Canada ruled that not providing sign language interpretation needed for effective communication in health care breached the Charter's equality rights.

Hearing loss is also widespread among people who do not identify as Deaf. In 2012 to 2015, about 38% of adults aged 20 to 79 had measured hearing loss and about 37% reported tinnitus in the past year (Statistics Canada, 2021). Only about 12% of adults with hearing loss used hearing aids. Cost is a commonly cited barrier, and hearing aid subsidies and eligibility vary by province (Feder et al., 2015). People with lower household income and less education had more hearing loss (Feder et al., 2015).

Access to interpreters is uneven. In rural, remote and northern communities, video remote interpreting may be the only option, and it depends on a reliable connection (Steinberg et al., 2006). The nurse asks which language a person uses, including an Indigenous sign language, rather than assuming ASL, and plans ahead for appointments and discharge teaching.

PRACTICE STORY

The Missing Hearing Aid

Names and details are fictional; this is a composite story.

Nurse: Fiona MacInnis, RN. Years in practice: 6. Setting: medical unit, Ontario.

Night report on Mr. Gilles Moreau, 83, admitted with a urinary tract infection, was short: "Pleasantly confused. Doesn't follow instructions. Tried to get up alone twice." The plan suggested a bed alarm and a geriatric psychiatry consult.

When I said good morning, he smiled and said, "Fine, fine." I asked whether he had pain, and he said, "Fine." Then I noticed he was watching my mouth and turning his left ear toward me. I stood in front of the window light, faced him and wrote on the whiteboard: "Can you hear me?" He laughed and wrote back, "Not without my hearing aids. They're in the top drawer at home."

I brought the unit's personal amplifier. Within minutes he told me his full name, where he was, why he had come in and that he had been getting up at night because he needed to urinate and no one answered his questions. He knew the date. I completed the delirium screen we use with him now able to hear me, and it was negative. I told the team I could not rule delirium out completely and that we would keep watching, but what we had seen fit a communication problem.

I called his daughter, who brought both hearing aids and the charger that afternoon. We put them in a labelled case on his bedside table. I updated the care plan: "Hard of hearing; hearing aids both ears; face him in good light; use amplifier if aids are out." I added it to the whiteboard and the handover tool, offered him a urinal and a bedside commode at night, and told the physician, who cancelled the psychiatry consult. At discharge teaching two days later, Mr. Moreau repeated back every step.

Reflect: What cues might the night team have missed, and how could the unit make hearing needs visible to everyone? Within authority, competence and context, when should an RPN caring for Mr. Moreau consult the RN?

36.6 Ear Disorders and Ear Surgery

Ear disorders range from a painful ear canal to sudden deafness and disabling vertigo. Many affect older adults and raise the risk of falls. This section covers common ear problems, balance disorders and nursing care after ear surgery. Falls prevention in full is in Chapter 8, and perioperative care in Chapter 7.

Common Ear Disorders

Otitis externa is infection or inflammation of the ear canal, often after water is trapped in the ear. Risks include swimming, overcleaning with swabs, skin conditions such as eczema, and hearing aids or earbuds that fit poorly or are not cleaned. The ear itches and feels full, and pain worsens when the outer ear is tugged; there may be drainage and muffled hearing. Treatment is careful cleaning of the canal and prescribed ear drops, sometimes with a wick if the canal is swollen shut. Older adults, people with diabetes and people with weakened immunity are at higher risk of a dangerous form that spreads to bone at the base of the skull (AAO-HNSF, 2018b). The nurse reports severe or spreading pain, fever or swelling around the ear (Figure 36.12).

Figure 36.12 Instilling ear drops in an adult: the patient lies with the affected ear up while the nurse gently pulls the pinna upward and backward to straighten the ear canal and holds the dropper tip clear of the skin. (credit: “Instilling ear medication” by British Columbia Institute of Technology (BCIT)/BCcampus, CC BY 4.0)

Otitis media, infection or fluid in the middle ear, is listed mainly as a cause of hearing loss in childhood (WHO, 2026). When fluid or infection fills the middle ear, sound cannot pass through well, so the result is a conductive loss (Table 36.3).

Sudden sensorineural hearing loss (SSNHL) is a rapid loss of hearing in one or both ears, developing over up to 72 hours; it is commonly defined as a loss of 30 decibels (dB) or more across three neighbouring pitches (AAO-HNSF, n.d.). More than 90% of cases have no known cause. The US guideline on sudden hearing loss asks clinicians to tell sensorineural from conductive loss at the first visit, so that a sudden nerve loss is not dismissed as wax. It recommends a hearing test as soon as possible and within 14 days, and corticosteroids may be offered within 2 weeks of onset (Chandrasekhar et al., 2019). Loss in both ears, repeated episodes or other neurologic signs call for prompt medical review, because they can point to other causes (Chandrasekhar et al., 2019); stroke is covered in Chapter 31. The nurse treats sudden hearing loss as urgent and arranges prompt medical assessment rather than a routine appointment.

Tinnitus is the perception of sound with no outside source (AAO-HNSF, 2026). It is common: about 37% of Canadian adults aged 20 to 79 reported tinnitus in the past year (Statistics Canada, 2021). The 2026 US guideline update focuses on bothersome tinnitus lasting 6 months or more. It calls for a full hearing evaluation and direct questions about distress and thoughts of self-harm, supports sound enrichment and cognitive behavioural therapy, and recommends against routine medicines or supplements (AAO-HNSF, 2026). New tinnitus in a person taking an ototoxic medicine is reported at once (section 36.4).

Wax that causes symptoms can be softened with drops, washed out by irrigation or removed by a trained clinician with suction or small instruments. Irrigation calls for caution, and removal by a specialist is preferred, when the eardrum has a hole or a tube, the

canal skin is damaged, or the person has diabetes or a weakened immune system (AAO-HNSF, 2018a). The nurse removes wax only as employer policy and competence allow (Scope in Practice box).

Vertigo and Balance Disorders

Vertigo is a false sense that the person or the room is moving (Bhattacharyya et al., 2017). Any new vertigo raises the risk of falls, and vertigo with new neurologic signs is assessed as a possible stroke (Chapter 31).

Benign paroxysmal positional vertigo (BPPV) is the most common inner ear balance disorder. Brief spells of vertigo, usually a minute or less, start with changes in head position, such as rolling over in bed, looking up or bending forward. Some people feel only light-headed, unsteady or nauseated. BPPV is more common in women and in middle and later life, and older adults with it have more falls; in one clinic study, about three quarters of older adults with undiagnosed BPPV had fallen in the previous 3 months. The diagnosis rests on the history and a positioning test done by a trained clinician. For the most common type (posterior canal BPPV), a US guideline strongly recommends a **canalith repositioning manoeuvre**, such as the Epley manoeuvre, done by a trained clinician; it recommends against routine use of vestibular suppressant drugs, such as antihistamines or benzodiazepines, and against activity restrictions after the manoeuvre. It also calls for checking factors that change management, such as poor balance, lack of support at home and fall risk, reassessment within a month and teaching about recurrence and safety (Bhattacharyya et al., 2017).

Ménière disease causes spontaneous vertigo attacks, each 20 minutes to 12 hours long, with sensorineural hearing loss, tinnitus and a feeling of pressure or fullness in the affected ear. Hearing may fluctuate. The diagnostic criteria were set by the Bárány Society with US and international partners (Lopez-Escamez et al., 2015) and are used in the 2020 US guideline. Onset peaks in the 40s and 50s. Short courses of vertigo-suppressing medicine are used only during attacks. Teaching covers diet and lifestyle changes that may reduce attacks. Diuretics or betahistine may be offered to prevent attacks, and injections into the middle ear or surgery are options when these fail. **Vestibular rehabilitation**, exercises that help the brain adapt to balance problems, is offered for ongoing imbalance but not during an acute attack, and people with hearing loss are counselled about hearing aids and assistive technology (Basura et al., 2020). Attacks come without warning, so the nurse helps the person plan for safety at home, at work and when driving. During an attack in hospital, the nurse keeps the person safe in bed with the call bell in reach, gives prescribed medicine for vertigo and nausea, and records how long the attack lasted and any change in hearing or tinnitus, since the guideline asks clinicians to track these outcomes (Basura et al., 2020).

Older adults carry more of the burden of ear disorders. Wax blocking the canal is more common with age (Feder et al., 2015), older age adds to the risk of hearing damage from aminoglycosides (Baxter Corporation, 2019), and older adults are more likely to develop the dangerous, spreading form of otitis externa (AAO-HNSF, 2018b). Older adults with BPPV have more falls, depression and difficulty with daily activities (Bhattacharyya et al., 2017), so the nurse links any dizziness to the falls plan (Chapter 8).

Ear Surgery

Tympanoplasty repairs a hole in the eardrum. **Stapedectomy** replaces a stapes that cannot move with a tiny piston; hearing improves in more than 90% of people (Royal Berkshire NHS Foundation Trust, 2022). Cochlear implant surgery places the internal part of the implant. Perioperative care is covered in Chapter 7.

After middle ear surgery, a dissolving or removable packing usually sits in the ear canal, and some blood-tinged drainage is expected for several days. To protect the repair, instructions from one Ontario surgeon include no nose blowing for 3 weeks, sneezing and coughing with the mouth open and no bending over for a week (Beyea, n.d.). A UK hospital's stapedectomy instructions add no straining, heavy lifting or constipation for 2 weeks (Royal Berkshire NHS Foundation Trust, 2022). Advice on flying varies widely, from 3 days after tympanoplasty in one Ontario handout to 5 weeks after stapedectomy in a UK leaflet, so the person follows their own surgeon's instructions (Beyea, n.d.; Royal Berkshire NHS Foundation Trust, 2022). Water is kept out of the ear.

Short-lived dizziness is expected, so fall precautions apply (Beyea, n.d.; Royal Berkshire NHS Foundation Trust, 2022). The facial nerve runs close to the middle ear (Royal Berkshire NHS Foundation Trust, 2022), so the nurse checks facial movement against the baseline, asking the person to raise the eyebrows, close the eyes tightly and smile (Chapter 30), and reports new weakness at once. A metallic taste on one side of the tongue may follow and usually settles over months (Beyea, n.d.). The nurse reports fever, heavy bleeding, foul or pus-like drainage, pain not relieved by the prescribed medicine, severe vertigo or vomiting and sudden loss of hearing (Beyea, n.d.; Royal Berkshire NHS Foundation Trust, 2022).

Table 36.4 summarizes the ear and balance disorders in this section and the nursing focus for each.

Table 36.4 Ear and balance disorders and nursing focus (AAO-HNSF, 2018b; AAO-HNSF, 2026; Basura et al., 2020; Bhattacharyya et al., 2017; Chandrasekhar et al., 2019)

Disorder	Key features	Danger signs to report	Nursing focus
Otitis externa	Itchy, full ear canal; pain when the outer ear is tugged; drainage	Severe or spreading pain, fever, swelling around the ear, especially in older adults or people with diabetes	Keep the ear dry; give ear drops as prescribed; teach avoiding cotton swabs
Sudden sensorineural hearing loss	Hearing loss developing over up to 72 hours in one or both ears	Any sudden loss; loss in both ears or with neurologic signs	Prompt medical assessment; do not assume wax; communication support
Tinnitus	Ringing, buzzing or hissing with no outside source	New tinnitus on an ototoxic medicine; distress or thoughts of self-harm	Ask about distress; hearing evaluation; sound enrichment; referral for counselling
Benign paroxysmal positional vertigo	Spells of vertigo of a minute or less with changes in head position	Vertigo with neurologic signs; falls	Fall precautions; help with getting up; repositioning manoeuvre by a trained clinician
Ménière disease	Vertigo attacks, each 20 minutes to 12 hours long, with fluctuating hearing loss, tinnitus and ear fullness	Falls during attacks; vomiting that prevents fluid intake	Safety during attacks; medicines as prescribed; diet and lifestyle teaching; hearing support

PATIENT EDUCATION

After Ear Surgery

Your surgeon will give you instructions for your own operation; follow them first. Common advice after middle ear surgery includes (Beyea, n.d.; Royal Berkshire NHS Foundation Trust, 2022):

- **Protect the repair:** do not blow your nose until your surgeon says you may. Sneeze and cough with your mouth open. Avoid bending over, straining and heavy lifting, and prevent constipation.
- **Keep water out:** keep the ear dry when you shower or wash your hair, as your surgeon shows you. Do not put cotton swabs in the ear. Leave any packing in place.
- **Expect some changes:** some blood-tinged drainage, popping sounds, mild dizziness and a metallic taste can happen and usually settle.
- **Stay safe:** get up slowly and hold on to something while you are dizzy. Do not drive until you can turn your head quickly without feeling unsteady.
- **Travel:** ask your surgeon before flying; advice ranges from days to weeks.
- **Call your surgeon or get help** for a fever (as your surgeon's instructions define it), heavy bleeding, pus or foul-smelling drainage, pain your medicine does not relieve, severe dizziness or vomiting, new weakness of your face, or sudden loss of hearing.

SCOPE IN PRACTICE

Eye and Ear Care and Who Does What

Every nurse assesses vision and hearing, provides communication access and acts at once on eye emergencies and sudden hearing loss. Who does more depends on authority, competence and context (College of Nurses of Ontario [CNO], 2025; Chapter 1, section 1.3).

- **Authority:** In Ontario, putting an instrument, hand or finger beyond the external ear canal is a controlled act authorized to RNs and RPNs; it needs an order unless the nurse may initiate it, and nurses cannot initiate controlled acts in public hospitals (CNO, 2025). Wax removal and ear irrigation work within the ear canal; the nurse follows employer policy and any order the setting requires. Prescription eye and ear drops are given with the order or prescription the setting requires (Chapter 1, section 1.3).
- **Competence:** Eye irrigation, cerumen removal and ear irrigation need knowledge, skill and judgment, including checking for reasons not to irrigate, such as a hole in the eardrum (section 36.6). A nurse without that competence asks for support.

- **Context:** Employer policy sets which nurses may remove wax or irrigate ears, and employers can limit but not expand a nurse's legislated scope (CNO, 2025).

Arranging a qualified interpreter and other communication supports is every nurse's duty. Any nurse who notices a chemical eye injury, sudden vision or hearing loss, or new tinnitus or dizziness on an ototoxic medicine acts at once and escalates; the RPN consults the RN as the patient's needs change. Rules differ by province and territory, and CNO's revised Scope of Practice and Medication standards take effect on March 1, 2027 (CNO, 2026).

Chapter 36 Summary

36.1 Vision and Eye Assessment

- The cornea and lens focus light on the retina; the macula gives central vision, and the optic nerve carries signals to the brain. Intraocular pressure reflects the balance between aqueous humour made and drained.
- Assessment covers usual vision and aids, sudden or gradual change, pain, flashes, floaters, halos and distortion, plus visual acuity and outer eye inspection. Gradual loss often goes unnoticed or unreported.
- In 2022, 7.4% of Canadians aged 15 and older reported a seeing disability, rising to 11.4% at age 65 and older.
- Care for people with low vision includes introductions, orientation, CNIB's sighted guide technique, accessible formats and falls prevention. Charles Bonnet syndrome can be mistaken for dementia or mental illness.

36.2 Cataract, Glaucoma and Other Causes of Vision Loss

- Cataract is clouding of the lens; day surgery replaces it with an intraocular lens. After surgery, teaching covers the shield, drops, activity limits and warning signs such as rising pain, redness and worsening vision.
- Open-angle glaucoma is silent until advanced; people at high risk need eye examinations. Drops lower intraocular pressure, and beta-blocker drops such as timolol can have serious systemic effects.
- Acute angle-closure glaucoma, with eye pain, headache, halos, blurred vision and vomiting, is an emergency.
- New distortion in AMD needs review within 24 hours; wet AMD is treated with anti-VEGF injections. Diabetes Canada sets retinopathy screening intervals by diabetes type.
- Colonization and other structural causes, plus distance from specialists, limit eye care access for many First Nations, Inuit and Métis people; community-designed teleophthalmology is one response.

36.3 Eye Emergencies, Trauma and Eye Surgery

- A chemical in the eye is irrigated at once and for a prolonged time. A penetrating injury is shielded without pressure, and any protruding object is left in place.
- Sudden flashes, new floaters and a spreading shadow suggest retinal detachment; sudden painless vision loss needs immediate escalation, with stroke and giant cell arteritis considered.
- Corneal abrasions are not patched, and numbing drops are not sent home.
- After retinal surgery with a gas bubble, the person follows positioning exactly, avoids lying flat on the back, does not fly, travel to higher elevations or receive nitrous oxide, and wears the alert wristband until the gas is gone.

36.4 Hearing and Ear Assessment

- The outer and middle ear carry sound to the cochlea, which turns it into nerve signals; the inner ear also senses balance.
- Conductive loss comes from the outer or middle ear and is often treatable; sensorineural loss comes from the cochlea or nerve and is usually permanent; mixed loss combines both.
- Presbycusis starts at high pitches, making speech sound mumbled, especially in noise; noise and ototoxic medicines are preventable causes.
- Aminoglycosides such as gentamicin can cause tinnitus, high-pitched hearing loss and balance damage, which may be permanent; the nurse reports new symptoms at once and supports drug level and kidney monitoring.

- In Canada, about 38% of adults aged 20 to 79 had measured hearing loss, and about 77% of adults aged 40 to 79 with measured loss did not perceive it, so the nurse asks every adult about hearing.
- The whispered voice test is a quick screen; wax, sudden loss and suspected hearing loss are followed up, and audiologists confirm loss with an audiogram.

36.5 Communication Access, Hearing Aids and Cochlear Implants

- Communication access underpins consent, teaching and safety; unaddressed hearing loss can be mistaken for confusion.
- The nurse asks how the person communicates best, faces them in good light, reduces noise, speaks a little louder and slower and checks understanding; personal amplifiers help when hearing aids are absent.
- Masks muffle sound and hide the lips; clear-window masks allow lip-reading but muffle sound more.
- Deaf people who sign need qualified ASL, LSQ or Indigenous sign language interpreters, in person or by video; family members do not interpret.
- The Accessible Canada Act recognizes signed languages, the Eldridge decision made interpretation in health care a Charter equality issue, and Ontario's AODA requires communication supports.
- Hearing aids and cochlear implant processors are recorded, kept in use, charged and stored safely; the MRI team must be told about a cochlear implant and its model.

36.6 Ear Disorders and Ear Surgery

- Otitis externa causes ear canal pain that worsens when the ear is tugged; older adults and people with diabetes are at higher risk of a dangerous spreading form.
- Sudden sensorineural hearing loss is urgent: it is not assumed to be wax, and hearing testing and any treatment start early.
- Bothersome tinnitus calls for a hearing evaluation and direct questions about distress and self-harm; routine medicines and supplements are not recommended.
- BPPV causes brief positional vertigo and is treated with a repositioning manoeuvre by a trained clinician; Ménière disease causes attacks of vertigo lasting hours with fluctuating hearing loss, tinnitus and ear fullness.
- After ear surgery, patients avoid nose blowing and straining, sneeze with the mouth open, keep water out of the ear and follow their surgeon's travel advice; new facial weakness, severe vertigo or sudden hearing loss are reported at once.
- Every nurse provides communication access and escalates eye and ear emergencies; cerumen removal and ear irrigation depend on authority, competence and employer policy.

Key Terms (57)

acute angle-closure glaucoma: An eye emergency in which the drainage angle closes and intraocular pressure rises quickly, causing eye pain, headache, halos, blurred vision, nausea and vomiting.

age-related macular degeneration (AMD): Age-related disease of the macula that causes loss of central vision; it occurs in a dry (atrophic) form and a wet (neovascular) form.

American Sign Language (ASL): A full signed language with its own grammar, used by many Deaf people in English-speaking Canada; recognized in the Accessible Canada Act as one of the primary languages of communication for deaf persons in Canada.

anti-VEGF therapy: Medicines that block vascular endothelial growth factor, injected into the eye to treat wet AMD and diabetic eye disease.

aqueous humour: The clear fluid made by the ciliary processes that fills the front of the eye and drains through the drainage angle and the uveoscleral route.

audiogram: A chart of the softest sounds a person can hear in each ear across a range of pitches, produced by a hearing test.

benign paroxysmal positional vertigo (BPPV): An inner ear disorder causing brief spells of vertigo, usually a minute or less, triggered by changes in head position.

canalith repositioning manoeuvre: A series of head and body movements, such as the Epley manoeuvre, done by a trained clinician to treat BPPV.

cataract: Clouding of the lens of the eye, most often with age.

cerumen: Earwax, made by glands in the outer ear canal to protect and lubricate the canal.

cerumen impaction: A build-up of earwax that blocks the ear canal or causes symptoms such as fullness, muffled hearing, tinnitus or ear pain.

Charles Bonnet syndrome: Seeing images of people, landscapes or patterns that are not there, after significant vision loss; it is often mistaken for dementia or a mental health problem.

chemical eye injury: Damage to the eye from a chemical splash; alkali injuries are generally more harmful than acid injuries.

cochlea: The fluid-filled, snail-shaped organ of the inner ear whose hair cells turn sound vibrations into nerve signals.

cochlear implant: An electronic device, partly placed by surgery, that sends signals straight to the hearing nerve so that people who are severely hard of hearing or profoundly deaf can perceive sound.

communication access: The ability of a person to understand and be understood in the way that works for them, with the supports they need.

conductive hearing loss: Hearing loss caused by a problem in the outer or middle ear that stops sound from reaching a normal inner ear.

cornea: The clear, curved front surface of the eye, which bends incoming light to help focus it.

corneal abrasion: A scratch in the outer layer of the cornea that causes pain, tearing and light sensitivity.

Deaf: A cultural identity, written with a capital D, of people who share Deaf culture and use a signed language as their main language.

diabetic retinopathy: Damage to the retina caused by diabetes.

endophthalmitis: A sight-threatening infection inside the eye that can follow eye surgery or a penetrating eye injury.

glaucoma: A group of eye diseases in which the optic nerve is progressively and irreversibly damaged and the visual field shrinks.

hearing aid: A small electronic device worn in or behind the ear that makes sound louder.

hyphema: Bleeding inside the front of the eye, usually after blunt injury; a possible sign of serious injury to the eyeball.

inner ear: The innermost part of the ear, containing the cochlea for hearing and the vestibular organs for balance.

intraocular pressure (IOP): The pressure inside the eye, set by the balance between aqueous humour production and drainage.

langue des signes québécoise (LSQ): A full signed language used by many Deaf people in Quebec and French-speaking communities; recognized in the Accessible Canada Act.

lens: The clear structure behind the pupil that works with the cornea to focus light onto the retina.

low vision: As used in this chapter, vision loss that cannot be fully corrected with glasses, contact lenses, medicine or surgery and that limits everyday activities.

macula: The central area of the retina that gives sharp central vision.

middle ear: The air-filled space behind the eardrum containing three small bones that carry sound vibrations to the inner ear.

mixed hearing loss: Hearing loss with both conductive and sensorineural parts.

Ménière disease: An inner ear disorder with vertigo attacks, each 20 minutes to 12 hours long, with sensorineural hearing loss, tinnitus and a feeling of fullness in the affected ear.

open-angle glaucoma: A slowly progressive form of glaucoma that typically causes no symptoms until it is advanced.

optic nerve: The nerve that carries signals from the retina to the brain.

otitis externa: Infection or inflammation of the ear canal, often after water is trapped in the ear; pain worsens when the outer ear is tugged.

otitis media: Infection or fluid in the middle ear, listed mainly as a cause of hearing loss in childhood; it causes a conductive hearing loss.

ototoxicity: Damage to the inner ear, affecting hearing, balance or both, caused by a medicine or chemical.

outer ear: The visible ear and the ear canal, ending at the eardrum.

personal amplifier: A small handheld device that makes nearby speech louder through headphones or earphones for a person with hearing loss.

presbycusis: Age-related sensorineural hearing loss that starts at the highest pitches and later spreads to lower ones.

punctal occlusion: Pressing on the inner corner of the eye after instilling a drop to reduce the amount of drug that reaches the bloodstream.

retina: The light-sensitive layer at the back of the eye, whose photoreceptor cells turn light into electrical signals.

retinal detachment: Separation of the retina from the back of the eye, signalled by sudden flashes, new floaters and a spreading shadow over vision.

sensorineural hearing loss: Hearing loss caused by damage to the cochlea or the hearing nerve; usually permanent.

sighted guide: A technique for walking with a person who is blind or partially sighted, in which the person holds the guide's arm just above the elbow and walks about half a step behind.

stapedectomy: Surgery that replaces a stapes bone that cannot move with a tiny piston to improve hearing.

sudden sensorineural hearing loss (SSNHL): A rapid sensorineural hearing loss developing over up to 72 hours, commonly defined as a loss of 30 dB or more across three neighbouring pitches; an urgent problem.

tinnitus: The perception of sound, such as ringing, buzzing or hissing, with no outside source.

tympanic membrane: The eardrum, the thin membrane at the end of the ear canal that vibrates with sound.

tympanoplasty: Surgery to repair a hole in the eardrum.

vertigo: A false sense that the person or the surroundings are moving.

vestibular rehabilitation: Exercises that help the brain adapt to balance problems; offered for ongoing imbalance but not during an acute attack of vertigo.

video remote interpreting (VRI): Sign language interpretation provided by an interpreter who joins by video on a screen.

visual acuity: The sharpness of vision at a set distance, often measured with a letter chart such as the Snellen chart.

whispered voice test: A bedside hearing screen in which the examiner, out of the person's sight, whispers a mix of numbers and letters for the person to repeat, testing each ear separately.

Licensure Review & Clinical Judgment Questions (40)

Questions tagged **[Core]** apply to all nursing students (NCLEX-RN, REx-PN, and CPNRE). Questions tagged **[RN]** draw on *Going Deeper* content.

Case: Mrs. Huguette Desrosiers (Questions 1–4): Mrs. Huguette Desrosiers, 72, had day-surgery cataract removal from her right eye this morning in Ontario. She lives with her husband, wears reading glasses and has type 2 diabetes. Her surgeon has ordered two kinds of eye drops for the right eye. The registered practical nurse (RPN) is completing her discharge teaching.

1. [CORE] The RPN teaches Mrs. Desrosiers how to use her two kinds of eye drops. Which statement shows that she has understood the teaching?

a. "I'll put both kinds of drops in one right after the other so I don't forget the second one before bedtime."

b. "I'll wash my hands, put one drop in the pocket of my lower lid, and wait before using the second kind of drop."

c. "I'll hold the bottle tip against my lower lid so the drop goes in the right place and doesn't run down my cheek."

d. "I'll rub my eye gently after each drop so the medicine spreads over the whole eye and starts working faster."

Answer: b — Clean hands, one drop into the lower-lid pocket, and a wait between different drops (5 minutes in the hospital's instructions) is correct technique (section 36.2, Cataract, and the Patient Education box). Option a skips the wait between different drops that the instructions require. Option c risks touching and contaminating the eye and the bottle tip. Option d is wrong because rubbing or pressing on the eye is avoided after cataract surgery.

2. [CORE] Mrs. Desrosiers asks how to use the plastic shield she was given. Which instruction is consistent with typical post-cataract instructions?

a. "Wear the shield only when you go outside for the next month, and leave it off when you are at home indoors."

b. "Put a folded gauze pad under the shield tonight so that it fits snugly and puts gentle pressure on the eye."

c. "You can stop wearing the shield tonight, once the eye feels comfortable and you can see better than before."

d. "Wear it all the time today except when putting in drops, then wear it at night for about the next week."

Answer: d — The Canadian instructions read for this chapter direct wearing the shield at all times on the day of surgery except during drops, then at night for the next 7 nights, always following the surgeon's instructions (section 36.2, Cataract). Option a gets the timing backwards; the shield protects the eye during sleep, when the person may rub it. Option b is unsafe because nothing is placed between the shield and the eye and pressure on the eye is avoided. Option c stops protection too early.

3. [CORE] Mrs. Desrosiers says she plans to get back to her garden and weed her flower beds this weekend. Which response by the RPN is best?

a. "Avoid gardening, heavy lifting and bending your head below your shoulders for about 2 weeks, or as your surgeon advises."

b. "Gardening is fine as long as you wear your sunglasses outdoors, since the main risk after this surgery is bright sunlight."

c. "You can garden right away if you kneel instead of bending, because kneeling takes the strain off the eye."

d. "Gardening is safe after 2 days, as long as you put in an extra dose of your antibiotic drops before you go outside."

Answer: a — Typical instructions restrict gardening and handling soil, lifting more than about 4.5 kg (10 lb), and bending the head below the shoulders for 2 weeks, with the surgeon's own instructions taking priority (section 36.2, Cataract). Option b ignores the infection risk from soil. Option c still exposes the eye to soil and dust. Option d adds an unordered dose and does not remove the risk.

4. [CORE] On the second day after surgery, Mrs. Desrosiers's husband calls the day-surgery unit. Which report needs the most urgent follow-up?

a. Her eye feels a little scratchy, and she has a small amount of watery tearing when she first wakes up in the morning.

b. She has trouble reading her newspaper and plans to wait for new reading glasses after her follow-up visit next week.

c. Her eye pain has been getting worse since last night, the eye is redder, and her vision in that eye seems blurrier.

d. She has worn her shield at night, has used her drops as directed, and says the eye feels comfortable today.

Answer: c — Rising pain, increasing redness and worsening vision after cataract surgery are warning signs that need prompt contact with the surgical team or an emergency department; they can signal a complication such as infection inside the eye (endophthalmitis) (section 36.2, Cataract). Options a and b describe common, non-urgent concerns that can be addressed at follow-up. Option d describes expected recovery with correct self-care.

5. [CORE] Mr. Idris Kamara, 58, has been blind since a workplace injury and walks with a white cane. He asks the nurse to walk with him to the patient lounge. Which action follows the sighted guide technique?

a. The nurse takes his elbow firmly from behind and steers him gently around chairs and other obstacles in the hallway.

b. The nurse holds the end of his white cane and walks in front of him so that he can follow the cane through the hallway.

c. The nurse lightly touches the back of his hand with her own, lets him hold just above her elbow, and walks half a step ahead.

d. The nurse walks beside him and calls out "left" or "right" whenever he starts to drift toward the hallway walls.

Answer: c — CNIB's sighted guide technique has the person hold the guide's arm just above the elbow and walk about half a step behind, after the guide signals by touching the back of the hand (section 36.1, Caring for People With Vision Loss). Option a pushes and steers him, which CNIB says never to do. Option b takes control of his cane, which should never be grabbed or pulled. Option d gives late directions without describing obstacles ahead.

6. [CORE] Which person has the most risk factors for open-angle glaucoma, as described in this chapter?

a. A 63-year-old man of African descent whose sister has glaucoma and who uses corticosteroid eye drops for eye inflammation

b. A 35-year-old woman with long-sightedness who wears contact lenses every day and works long hours at a computer screen

c. A 45-year-old man who had cataract surgery in one eye last year and who now wears reading glasses for close work at his desk

d. A 50-year-old woman with seasonal allergies who takes an antihistamine tablet daily and uses lubricating eye drops each spring

Answer: a — Older age, African descent, a first-degree relative with glaucoma and corticosteroid use in or around the eye are all risk factors for open-angle glaucoma (section 36.2, Glaucoma). Option b is younger, and long-sightedness is a risk factor for angle closure rather than open-angle glaucoma. Option c describes cataract surgery and age-related reading glasses, which are not listed risk factors. Option d describes allergy treatment, not a listed risk factor.

7. [CORE] A patient starting latanoprost eye drops for glaucoma asks about side effects. Which teaching is accurate?

a. The drops often cause a dry mouth and drowsiness, so the patient should avoid driving for the first month of treatment.

b. The drops can slow the heart rate and cause wheezing, so the patient should check their pulse before every single dose.

c. The drops may leave a bitter taste in the mouth and should be stopped right away if the taste becomes unpleasant.

d. The drops may gradually darken the coloured part of the eye, and this change is likely to be permanent if it occurs.

Answer: d — The latanoprost monograph warns that darkening of the iris increases with continued use and probably will not reverse after the drug is stopped; the eyelashes may also change (section 36.2, Glaucoma). Option a describes brimonidine. Option b describes systemic effects of beta-blocker drops such as timolol. Option c describes dorzolamide, and no drop is stopped without the prescriber's advice.

8. [CORE] Why does the nurse teach a patient to press on the inner corner of the eye for 2 minutes after instilling timolol drops?

a. To stop the drop from stinging the surface of the eye as it spreads across the cornea

b. To reduce how much of the drug drains into the nose and reaches the bloodstream

c. To keep the eyelid closed so the patient does not blink the drop out right away

d. To lower the pressure inside the eye by pushing aqueous humour out of the eye

Answer: b — Nasolacrimal (punctal) occlusion or gentle eyelid closure for 2 minutes reduces systemic absorption, which matters for beta-blocker drops (section 36.2, Glaucoma, and the Going Deeper box). Option a confuses occlusion with comfort measures. Option c describes eyelid closure, not the purpose of pressing on the inner corner. Option d is wrong: pressing on the eye does not treat glaucoma, and pressure on the eye is avoided after eye surgery.

9. [CORE] Ms. Colleen Ouellette, 77, has wet age-related macular degeneration and receives regular eye injections. During a home visit, she tells the nurse that since yesterday the lines on her Amsler grid look bent in her left eye. Which action is best?

a. Advise her to contact her eye specialist today, because new distortion needs review within 24 hours.

b. Reassure her that bent lines are expected with macular degeneration and record the change in her chart.

c. Suggest she stop checking the grid, since it is not accurate and is likely to make her feel more anxious.

d. Tell her to mention the change at her next scheduled injection appointment, which is in 3 weeks' time.

Answer: a — New distortion or central blur in AMD is urgent and needs review by an eye specialist within 24 hours, because wet AMD can progress quickly (section 36.2, Macular Degeneration and Diabetic Retinopathy). Option b treats a new change as expected. Option c removes a self-monitoring tool that is still recommended despite its limits. Option d delays assessment.

10. [CORE] Mr. Ruben Ramírez, 52, was diagnosed with type 2 diabetes last month. Which statement about retinopathy screening is consistent with Diabetes Canada's guideline?

a. "You won't need an eye examination until you have had diabetes for 5 years, unless your vision changes."

b. "Your family doctor will check your eyes with a light at your yearly physical, and that is all the eye screening you will need."

c. "You should have a retinal examination now, then every 1 to 2 years if no retinopathy or only minimal retinopathy is found."

d. "You need an eye examination every 3 months for the first year, because newly diagnosed diabetes damages the retina quickly."

Answer: c — For type 2 diabetes, Diabetes Canada recommends screening at diagnosis by an optometrist or ophthalmologist, then every 1 to 2 years when there is no or minimal retinopathy (section 36.2). Option a describes the start of screening in type 1 diabetes. Option b is wrong because screening is done by an optometrist or ophthalmologist, who examines the eye directly or reads retinal photographs taken after the pupils are dilated. Option d is not a recommended interval.

11. [CORE] A cleaner on a hospital unit splashes a disinfectant concentrate into her eyes and calls for help. What is the nurse's first action?

a. Find the product's safety data sheet to identify the chemical before choosing which eye treatment to use

b. Cover both eyes with dry gauze pads and walk her straight down to the emergency department for an urgent assessment

c. Call the most responsible provider for an order for anesthetic eye drops before touching or rinsing her eyes

d. Begin flushing her eyes with water or saline at once, holding the lids open, and keep going while help is called

Answer: d — Chemical eye injury is irrigated immediately and for a prolonged time, with the eyelids held open; irrigation is not delayed to identify the chemical or obtain orders (section 36.3, Eye Emergencies). Options a and c delay irrigation, and option b covers the eyes without removing the chemical.

12. [CORE] A patient arrives in the emergency department with a small metal fragment protruding from the right eye after using a grinder. Which action is appropriate while waiting for ophthalmology?

a. Remove the fragment carefully with sterile forceps so that it cannot be pushed any further into the eye during transfer

b. Tape a rigid shield over the eye so it does not touch the fragment or press on the eye, and give the ordered antiemetic

c. Apply a firm pressure patch over both eyes to stop eye movement and to reduce any bleeding from inside the injured eye

d. Irrigate the eye with large volumes of saline to wash out any small metal particles left around the protruding fragment

Answer: b — With a penetrating injury, the eye is covered with a rigid shield without pressure, a protruding object is left in place, and vomiting and straining are prevented (section 36.3, Eye Emergencies). Option a risks further damage to the eye. Option c puts pressure on an injured eye. Option d is used for chemical injury, not a penetrating injury.

13. [CORE] An RPN on a surgical unit is caring for Mrs. Agnes Gallant, 66. At 2100 she says she has seen sudden flashes of light and "a swarm of black specks" in her left eye for the past hour, and a grey shadow is creeping across the top of her vision. What should the RPN do?

a. Consult the RN and notify the most responsible provider now, because these are warning signs of retinal detachment.

b. Dim the lights, encourage her to rest her eyes, and reassess her vision after she has had a full and restful night's sleep.

c. Explain that floaters are common with age, and suggest she mention them at her next visit to her optometrist.

d. Instil lubricating eye drops from her supply and document the symptoms for the day team to review in the morning.

Answer: a — Sudden flashes, new floaters and a spreading shadow over vision suggest retinal detachment and need assessment within 24 hours; the RPN acts at once, consults the RN and escalates (section 36.3, Eye Emergencies). Options b, c and d all delay assessment, and option d also treats with a product that will not help.

14. [CORE] A patient was diagnosed with a corneal abrasion after a branch scratched his eye. He asks whether he can take home the numbing drops used during his examination. Which response is accurate?

a. "Yes, use them whenever the pain comes back, because they will help the scratch heal more quickly."

b. "Yes, but only at bedtime, so the pain does not wake you up during the night while the eye heals."

c. "You can use them for the first 2 days only, and then switch to a regular pain reliever by mouth."

d. "No, numbing drops are not used at home because they slow healing and can hide signs of worsening."

Answer: d — Topical anesthetic drops are not recommended for home use because they are toxic to the corneal surface, delay healing and mask worsening symptoms (section 36.3, Eye Emergencies). Options a, b and c all send the patient home with numbing drops, and option a wrongly claims they speed healing.

15. [CORE] An RPN in a long-term care home finds Mr. Walter Abernathy, 81, upset because he "suddenly can't see anything" out of his right eye. He has no eye pain. His vital signs are within his usual range. What is the RPN's priority?

a. Clean his glasses, improve the lighting in his room, and recheck his vision later in the shift once he has calmed down.

b. Arrange an appointment with his optometrist for the next available date and continue to monitor him until then.

c. Consult the RN and contact the physician or NP immediately, because sudden painless vision loss is an emergency.

d. Document the new finding in his chart and ask the next shift to reassess his vision in the morning after breakfast.

Answer: c — Sudden painless vision loss may mean a blocked retinal artery, stroke or giant cell arteritis; it needs immediate escalation and ophthalmology referral (section 36.3, Eye Emergencies; Chapters 31 and 34). The RPN acts at once and consults the RN as needs change. Options a, b and d delay assessment of an emergency.

16. [CORE] The nurse is caring for a patient who has low vision from glaucoma and is newly admitted to a medical unit. Which actions support the patient's safety and independence? Select all that apply.

a. Say your name and role each time you enter the room, and tell the patient when you are leaving.

b. Move the patient's belongings to the places staff usually keep them so that everything is easy for staff to find.

c. Describe the layout of the room, including the call bell, bed controls and the route to the bathroom.

d. Ask the patient which formats they prefer for written information, such as large print or audio.

e. Speak to the patient's daughter instead of the patient when explaining the plan of care, to save time.

f. Keep the path to the bathroom clear and well lit, and keep the patient's glasses within reach.

Answer: a, c, d, f — Introducing yourself and saying when you leave, orienting the patient to the room, offering accessible formats and keeping a clear, lit path with glasses within reach support safety and independence (section 36.1, Caring for People With Vision Loss). Option b is wrong because items are kept where the patient puts them. Option e is wrong because the nurse speaks directly to the patient.

17. [CORE] Mrs. Odile Sauvé, 84, has advanced macular degeneration. She tells the nurse that she keeps seeing small children in old-fashioned clothes standing in the corner of her room, although she knows they cannot really be there. She is alert and oriented. Which response is most appropriate?

a. "These images can be a sign of a new mental illness, so I will ask for a psychiatric consultation to be booked for you today."

b. "Some people with vision loss see images that aren't there. I'll let your team know, and we can talk about supports."

c. "It is probably a side effect of your eye injections, so you should cancel your next injection appointment."

d. "You are probably becoming confused at night, so I will keep the lights off to help you sleep better."

Answer: b — Images of people or patterns that are not there, in an alert, oriented person with significant vision loss, fit Charles Bonnet syndrome; it is often mistaken for dementia or a mental health problem (section 36.1). The nurse listens without judgment, reports it and connects the person with support. Option a assumes mental illness. Option c gives unsafe advice about stopping treatment. Option d assumes confusion, and darkness does not help.

18. [RN] An RN on a medical unit assesses a 69-year-old patient who has sudden severe pain in the left eye, a headache, vomiting and blurred vision with halos around lights. The left pupil is mid-dilated and reacts poorly. Earlier that day the patient received an anticholinergic medicine. Which action is the priority?

a. Give an analgesic for the headache, dim the room lights, and reassess the pain and the vision in the left eye in about an hour.

b. Instil the patient's lubricating eye drops and place a cool compress over the left eye to relieve the pain and the redness.

c. Give the next scheduled dose of the anticholinergic medicine, then document the eye findings for the team.

d. Notify the most responsible provider and ophthalmology at once, and prepare to give ordered pressure-lowering medicines.

Answer: d — Eye pain, headache, vomiting, halos and a mid-dilated, poorly reactive pupil suggest acute angle-closure glaucoma, an emergency that needs prompt IOP-lowering treatment followed by laser iridotomy; a pupil-dilating medicine may have triggered it (section 36.2, Glaucoma). Option a delays treatment of an emergency. Option b treats symptoms only. Option c gives more of a possible trigger.

19. [RN] A patient with COPD and type 2 diabetes is ordered timolol eye drops for open-angle glaucoma. Before the first dose, the RN finds a heart rate of 48 beats per minute. What is the best action?

a. Hold the dose and contact the prescriber, because timolol can be absorbed systemically and is contraindicated here.

b. Give the dose as ordered, because eye drops act only in the eye and do not affect the heart rate or breathing.

c. Give the dose and press on the inner corner of the eye for 2 minutes, which removes all risk of systemic effects from the drug.

d. Give half the dose to each eye so that the total amount of drug absorbed into the bloodstream is reduced.

Answer: a — The Canadian timolol monograph states that the drug may be absorbed systemically and lists COPD and sinus bradycardia among its contraindications; beta-blockers can also mask the signs of hypoglycemia (section 36.2, Glaucoma). Option b ignores systemic absorption. Option c is wrong because punctal occlusion reduces, but does not remove, absorption. Option d changes the order without authority.

20. [RN] A patient had vitrectomy with a gas bubble for retinal detachment 10 days ago and is now admitted for an urgent laparoscopic cholecystectomy under general anesthesia. She is wearing a gas bubble wristband. Which action by the RN is most important?

a. Remove the wristband before surgery, because all jewellery and bands must come off before going to the operating room.

b. Position her flat on her back after surgery to reduce strain on the new abdominal incisions.

c. Make sure the anesthesia and surgical teams know about the gas bubble, because nitrous oxide must not be used.

d. Ask the surgical team to cancel the upcoming eye follow-up visit, because it is not relevant to this hospital admission.

Answer: c — Until an intraocular gas bubble has dissolved, nitrous oxide can raise the pressure in the eye and cause blindness; the wristband alerts staff and stays on, and the anesthesia team must be told (section 36.3, Care After Eye Surgery). Option a removes the alert. Option b breaks her positioning instructions, since lying flat on the back is avoided. Option d ignores ongoing eye care that is still needed.

Case: Elias Vogt (Questions 21–26): Elias Vogt, 74, is admitted to a medical unit in a small Ontario hospital with community-acquired pneumonia and started on IV antibiotics, including gentamicin. He lives with his wife and normally wears hearing aids in both ears, but they were left at home in the rush to the hospital. The night nurse reports that he "seems confused": he answered "yes" to most questions, gave the wrong year when asked his date of birth and got out of bed without calling. On the day shift he is awake, watches the nurse's face closely when spoken to and often says "What?" He coughs up yellow sputum. Vital signs: temperature 37.8 °C, heart rate 92, respiratory rate 20, blood pressure 132/78 mm Hg and oxygen saturation 94% on 2 L/min by nasal prongs. His admission serum creatinine is 98 µmol/L.

21. [CORE] Which findings should the nurse recognize as cues that a hearing problem may explain Mr. Vogt's apparent confusion? Select all that apply.

a. His hearing aids were left at home.

b. He watches the nurse's face closely when spoken to.

c. He often says "What?" during conversation.

d. He answered "yes" to most questions overnight.

e. His temperature is 37.8 °C.

f. His oxygen saturation is 94% on 2 L/min.

g. He coughs up yellow sputum.

Answer: a, b, c, d — Hearing aids left at home, watching the speaker's face (lip-reading), asking "What?" and answering "yes" to everything are cues that he may not be hearing the questions (a, b, c, d; sections 36.4 and 36.5). The low-grade fever and oxygen saturation are cues about the pneumonia and raise his delirium risk, but they do not point to a hearing problem (e, f). Yellow sputum is a cue about the infection, not about hearing (g).

22. [CORE] Which interpretation of Mr. Vogt's overnight behaviour is most accurate?

a. His answers confirm delirium caused by pneumonia, so the nurse asks for a sedative to keep him in bed tonight.

b. His answers show long-standing dementia, so the nurse records it and simplifies all teaching from now on.

c. He may not be hearing questions, so the nurse restores communication first and then screens for delirium.

d. His answers are expected at his age and during an infection, so no further assessment is needed at this time.

Answer: c — Unaddressed hearing loss can look like confusion, so the nurse first makes sure he can hear (amplifier, facing him, hearing aids brought in) and then screens for delirium, which is still possible with pneumonia (c; section 36.5; Chapter 8). Labelling him delirious and sedating him without checking communication risks harm (a). Nothing supports a diagnosis of dementia (b). Confusion is never assumed to be normal for age (d).

23. [CORE] On day 4, Mr. Vogt's daughter has brought his hearing aids and he is oriented. He now reports a constant ringing in both ears, says he feels dizzy and unsteady when he stands and nearly fell walking to the bathroom. His serum creatinine has risen from 98 to 156 µmol/L. Which concern should the nurse treat as the priority?

a. Damage to the inner ear from gentamicin, affecting hearing and balance and raising his risk of falls

b. Hearing aids with low batteries, which can produce whistling sounds that the patient hears as a ringing noise

c. Worry about being in hospital, which can make a person notice ringing in the ears and feel light-headed

d. Weakness from several days of lying in bed, which can make a person unsteady when standing to walk

Answer: a — New tinnitus, dizziness and unsteadiness in a patient on an aminoglycoside, with worsening kidney function that raises drug levels, point to ototoxicity, and the near-fall makes it urgent (a; section 36.4). Battery problems do not explain dizziness, unsteadiness or a rising creatinine (b). Anxiety does not account for the full picture or the creatinine rise (c). Deconditioning may add to unsteadiness but does not explain the tinnitus (d).

24. [CORE] Which actions should the nurse include in Mr. Vogt's plan of care now? Select all that apply.

a. Report the tinnitus, dizziness and rising creatinine to the prescriber promptly.

b. Tell him the ringing is a normal part of pneumonia and will go away on its own.

c. Put fall precautions in place, including help with walking and the call bell within reach.

d. Make sure the latest gentamicin levels and kidney function results are available for review.

e. Take out his hearing aids for the rest of the day so that his ears can rest.

f. Ask about hearing changes in each ear and document what he reports.

g. Encourage him to walk to the bathroom alone to rebuild his strength.

Answer: a, c, d, f — The nurse reports signs of ototoxicity and the rising creatinine at once, has drug levels and kidney results ready, keeps him safe from falls and documents his hearing symptoms (a, c, d, f; sections 36.4 and 36.6). Ringing is not a normal part of pneumonia, and false reassurance delays action (b). Removing his hearing aids takes away his communication access without treating anything (e). Walking alone while dizzy invites a fall (g).

25. [RN] The trough gentamicin level drawn before Mr. Vogt's next dose is 3.1 mcg/mL; the product monograph advises avoiding troughs above 2 mcg/mL. The dose is due in 30 minutes. What should the nurse do first?

a. Give the dose on time, since a missed dose could let the pneumonia worsen, and report the level at morning rounds.

b. Contact the prescriber before the dose is due and report the level, creatinine, tinnitus and dizziness using SBAR.

c. Give half of the dose, since the trough is only a little above target, and ask for another level tomorrow morning.

d. Ask the pharmacist to replace gentamicin with an antibiotic that does not harm hearing, then give the new drug.

Answer: b — A high trough, rising creatinine and new symptoms of ototoxicity need the prescriber's decision before another dose; SBAR gives a clear, complete report (b; section 36.4; Chapter 6). Giving the dose risks permanent hearing and balance damage (a). The nurse does not change a dose without an order (c). The pharmacist can help, but changing the antibiotic needs a prescriber's order, and the prescriber must be told first (d).

26. [CORE] Gentamicin is stopped and another antibiotic started. Before discharge, which statement by Mr. Vogt shows that the teaching was effective?

a. "The ringing means my hearing aids are wearing out, so I will buy a new pair once I get home."

b. "Now that the antibiotic has been stopped, my hearing and balance are sure to be back to normal within a week."

c. "I will stay in bed most of the day at home until the dizziness is completely gone, to be safe."

d. "I will tell my doctor and pharmacist that gentamicin affected my ears and report any new hearing change."

Answer: d — He should make sure his providers know about the ototoxic reaction so it can be avoided in future, and report new or worse symptoms (d; section 36.4). The ringing is from the drug, not the hearing aids (a). Ototoxic damage may be permanent and can even appear after the drug is stopped, so full recovery cannot be promised (b). Staying in bed causes deconditioning; safe, supported activity and follow-up are better (c).

27. [CORE] An 80-year-old woman reports that hearing in her right ear has become gradually muffled. Otoscopy shows the right ear canal completely blocked by wax. Which statement about her hearing loss is most accurate?

a. It is a conductive loss, because sound cannot reach the inner ear; it often improves once wax is removed.

b. It is a sensorineural loss, because the wax has damaged the hair cells in the cochlea and the loss is permanent.

c. It is a mixed loss, because any hearing loss in a person over 80 combines nerve damage with a blockage.

d. It is age-related hearing loss, because wax build-up is the first stage of presbycusis in older adults.

Answer: a — Impacted wax blocks sound in the outer ear, a conductive loss that often improves when the wax is removed (a; section 36.4, Table 36.3). Wax does not damage the hair cells (b). A mixed loss needs both components and is not assumed from age (c). Presbycusis is sensorineural damage that starts at high pitches; it is not caused by wax (d).

28. [CORE] The nurse screens a patient's hearing with the whispered voice test. Which technique is correct?

a. Stand in front of the patient at a distance of 3 metres and whisper a short sentence while the patient watches.

b. Whisper a series of single numbers into each ear from 15 cm away while the patient keeps both eyes closed.

c. Stand beside the patient and say a mix of words in a normal voice, testing both ears together to save time.

d. Stand about an arm's length behind the patient, mask the other ear and whisper a mix of numbers and letters.

Answer: d — The test is done from about arm's length behind the person, so they cannot lip-read, with the other ear masked and a mix of numbers and letters whispered after a quiet breath out (d; section 36.4). Standing in front allows lip-reading (a). Whispering close to the ear is not the arm's-length method the review describes, and the other ear is not masked (b). A normal voice and testing both ears together miss a loss in one ear (c).

29. [CORE] A patient who is hard of hearing does not use sign language and is having trouble following the admission questions. Which approach by the nurse is best?

a. Raise the voice to a shout so the patient can hear, and stand at the side nearest the better ear.

b. Ask the patient's adult son to answer the questions, since he knows the history and hears well.

c. Face the patient in good light, turn off the television and check understanding as the talk goes on.

d. Give the patient the admission form to complete alone and collect it at the end of the shift.

Answer: c — Facing the person in good light, reducing noise, speaking a little louder and slower and checking understanding all support communication (c; section 36.5). Speaking a little louder and slower is enough, and standing to the side hides the face and lips the patient may rely on (a). The patient can take part and has the right to answer for himself (b). A form alone gives no chance to clarify or check understanding (d).

30. [CORE] Odette Lavallée, 58, is Deaf and uses langue des signes québécoise (LSQ). She is to sign consent for surgery tomorrow, and her hearing son offers to interpret for the consent discussion. What is the nurse's best response?

a. Thank him, explain that a qualified LSQ interpreter will be booked in person or by video, and invite him to stay.

b. Accept his offer, because a family member knows her best and can explain the surgery in words she will understand.

c. Write the consent discussion out in English for her to read, since written notes avoid the need for an interpreter.

d. Ask the surgeon to postpone the consent discussion until a family member who signs better than her son is available.

Answer: a — Consent needs a qualified, impartial interpreter; family interpreting can leave the patient out of the conversation and reduces privacy, but family can stay as support (a; section 36.5). Family members are not used as interpreters (b). Written notes are not a substitute for an interpreter for a Deaf person whose first language is signed (c). Another family member is still not a qualified interpreter (d).

31. [CORE] Which actions help keep a hospitalized patient's hearing aids in use and prevent their loss? Select all that apply.

a. Record the devices, and which ears they are for, at admission.

b. Store them in a labelled container kept in the same place each time.

c. Wrap them in a tissue on the meal tray when the patient eats.

d. Check that the batteries are charged or replaced.

e. Take them out during teaching sessions to avoid feedback noise.

f. Check that they are still in place after removing a mask.

g. Keep them in the bedside drawer for the whole stay for safety.

Answer: a, b, d, f — Recording devices, using a labelled container in a set place, keeping batteries working and checking devices after mask removal all keep hearing aids working and found (a, b, d, f; section 36.5). A device wrapped in tissue on a meal tray can easily be thrown out with the tray (c). Hearing aids should be in during teaching, when hearing matters most (e). Devices left in a drawer do not help the patient hear (g).

32. [CORE] A patient with a cochlear implant is booked for magnetic resonance imaging (MRI) of the knee. What should the nurse do?

a. Cancel the MRI, because people with cochlear implants can never have magnetic resonance imaging of any part of the body.

b. Tell the MRI team about the implant and give them the implant card, brand and model so they can check its conditions.

c. Remove the implant's magnet at the bedside before the patient goes to the MRI department, then replace it afterward.

d. Send the patient to the MRI department without comment, because a scan of the knee is far from the implant in the head.

Answer: b — Many implants are MR Conditional; the MRI team needs the brand and model to follow the manufacturer's conditions (b; section 36.5). Some implants allow MRI under set conditions, so an MRI is not automatically ruled out (a). Magnet removal, when needed, is surgical and not a nursing task (c). The implant's conditions apply to any MRI, not only scans of the head (d).

33. [CORE] Rosalind Okonjo, 67, reports brief spells of spinning, each lasting less than a minute, when she rolls over in bed or looks up. She has no hearing change or other symptoms. Which teaching is most appropriate?

a. "These spells are caused by fluid pressure in the inner ear, so you should cut back on salt and caffeine."

b. "You will need medicine every day to stop the spinning, and you should avoid moving your head until it settles."

c. "This is a sign of hearing loss, so an audiology appointment is the main thing needed to treat the spinning."

d. "A trained clinician can do a head-positioning treatment; until then, get up slowly and hold on to something."

Answer: d — Brief vertigo triggered by head position fits BPPV; a repositioning manoeuvre done by a trained clinician is the recommended treatment, and fall safety matters (d; section 36.6). Diet changes are taught for Ménière disease, not BPPV (a). Vestibular suppressant drugs are not routinely used, and restrictions are not recommended (b). Her symptoms come from the balance organs, and an audiology visit alone would not treat them (c).

34. [CORE] Ines Ferland, 46, is being assessed for Ménière disease. Which history best fits this diagnosis?

a. Spells of vertigo lasting a few seconds whenever she turns her head quickly, with normal hearing between spells

b. Constant unsteadiness for several months with no spinning, no change in hearing and no tinnitus at any time

c. Attacks of vertigo lasting several hours, with fluctuating hearing loss, tinnitus and fullness in one ear

d. A single episode of hearing loss in both ears on waking, with a headache and new weakness of one arm

Answer: c — Ménière disease causes repeated vertigo attacks, each 20 minutes to 12 hours long, with sensorineural hearing loss, tinnitus and ear fullness, and hearing may fluctuate (c; section 36.6). Seconds-long, position-triggered vertigo suggests BPPV (a). Constant unsteadiness without these features does not fit (b). Sudden loss in both ears with neurologic signs needs urgent assessment for other causes such as stroke (d).

35. [CORE] After a tympanoplasty, which statement by the patient shows understanding of the discharge teaching?

a. "I'll blow my nose gently each morning so that the pressure in my ear stays even."

b. "If I need to sneeze, I'll keep my mouth open, and I won't blow my nose yet."

c. "I'll clean the ear canal with a cotton swab after showering to keep it dry."

d. "I'll pull the packing out of my ear canal if it starts to feel itchy or loose."

Answer: b — Sneezing with the mouth open and not blowing the nose protect the repair (b; section 36.6, Patient Education box). Nose blowing is avoided for weeks (a). Swabs are not put in the ear (c). Packing is left in place unless the surgeon says otherwise (d).

36. [CORE] The day after a stapedectomy on the right ear, the patient cannot close the right eye fully and the right side of the mouth droops when smiling. Both were normal before surgery. What should the nurse do?

a. Report the new facial weakness to the surgeon at once, describing the baseline and the change found.

b. Record the findings and recheck facial movement at the next routine assessment in four hours.

c. Reassure the patient that facial droop is an expected short-term effect of all ear surgery.

d. Place a patch over the right eye to protect it and ask the patient to rest quietly until the weakness settles.

Answer: a — The facial nerve runs close to the middle ear, and new facial weakness after ear surgery is reported at once (a; section 36.6). Waiting four hours delays assessment (b). Facial weakness is not an expected effect (c). Eye protection may be ordered, but the change must be reported first (d).

37. [CORE] On a medical unit in Ontario, an RPN is asked to irrigate the ears of a patient with impacted wax. Employer policy allows RPNs with the required education to irrigate ears, and the RPN has completed it. The patient has diabetes and a history of a hole in the left eardrum. What should the RPN do?

a. Irrigate both ears as asked, since the RPN has the education and the employer's policy permits it.

b. Irrigate only the right ear, since the hole is on the left, and leave the left ear for the physician.

c. Hold the irrigation and report the history to the RN or prescriber, since both call for caution with irrigation.

d. Remove the wax from both ears with a small instrument instead, since this avoids water in the ear.

Answer: c — Competence includes judgment about when not to act; a perforated eardrum and diabetes call for caution with irrigation, and removal by a specialist is preferred, so the RPN holds the procedure and consults (c; section 36.6, Scope in Practice box). Policy and training do not override these cautions (a). Diabetes calls for caution in either ear (b). Manual removal with instruments is done by a trained clinician, not substituted without an order and competence (d).

38. [CORE] Bogdan Kostiuk, 61, has had constant tinnitus for 8 months. He tells the nurse, "I can't take this noise anymore. Some nights I don't see the point of anything." What should the nurse do first?

a. Suggest he play quiet background sound at night, which many people find makes the noise easier to bear.

b. Explain that tinnitus is common and usually fades over time, so he can expect it to be gone soon.

c. Refer him to audiology for a full hearing evaluation and to discuss whether hearing aids could help.

d. Ask him directly whether he has had thoughts of harming himself or ending his life, and stay with him.

Answer: d — His words suggest distress and possible suicidal thoughts; the 2026 tinnitus guideline update calls for asking directly about thoughts of self-harm, and safety comes first (d; section 36.6). Sound enrichment can help later but does not address risk (a). False reassurance dismisses his distress (b). A hearing evaluation is part of care but is not the first action here (c).

39. [RN] An audiogram shows the following. Right ear: air conduction thresholds of 45 to 50 dB HL at all frequencies; bone conduction thresholds of 10 dB HL. Left ear: air and bone conduction thresholds of 15 dB HL at all frequencies. Which interpretation is correct?

a. Sensorineural hearing loss in the right ear, because the air conduction thresholds are lower on the chart

b. Mixed hearing loss in the right ear, because both air and bone conduction thresholds are abnormal

c. Sensorineural hearing loss in both ears, because the left ear thresholds are also above 10 dB HL

d. Conductive hearing loss in the right ear, because bone conduction is normal and there is an air–bone gap

Answer: d — Normal bone conduction with poorer air conduction in the same ear (an air–bone gap) shows that the inner ear works and the problem lies in the outer or middle ear (d; section 36.4, Going Deeper box). Sensorineural loss would lower bone conduction too (a). Bone conduction of 10 dB HL is normal, so the loss is not mixed (b). Thresholds of 15 dB HL are within normal limits (c).

40. [RN] Marguerite Kowal, 52, calls the clinic. She woke this morning with muffled hearing and ringing in her left ear. She thinks it is wax and plans to use softening drops for a week before seeing anyone. Which response by the nurse is best?

a. "Softening drops are a safe first step; if your hearing has not improved after the week, book a routine appointment."

b. "Sudden hearing loss in one ear needs prompt medical care, to tell a nerve problem from wax so treatment is not delayed."

c. "Ringing with hearing loss is usually caused by stress, so try to rest and call us back if it is still there in a month."

d. "Sudden hearing loss is always permanent, so there is no need to rush; an audiology test can be done in a few months."

Answer: b — Sudden hearing loss is urgent; the guideline asks clinicians to tell sensorineural from conductive loss at the first visit, test hearing as soon as possible and offer any treatment early, within 2 weeks of onset (b; section 36.6). Waiting a week assumes wax and delays care (a). Stress is not a safe explanation (c). Recovery is possible and timing matters (d).

A Adult Canadian SI Reference Laboratory Intervals

Canadian clinical laboratories report hematologic, biochemical, and endocrine analytes using Système International (SI) units (**mmol/L**, **µmol/L**, **g/L**, and **× 10^9/L**) harmonized with the Canadian Society of Clinical Chemists (CSCC) and Medical Council of Canada reference intervals. Always verify patient results against the local hospital laboratory's specific assay reference range.

Analyte	Specimen	Adult SI Reference Interval	Critical / Escalation Threshold	Primary Chapters
Sodium (Na^+)	Serum / Plasma	**135–145 mmol/L**	< 120 or > 160 mmol/L	Ch. 3, 27, 30
Potassium (K^+)	Serum / Plasma	**3.5–5.0 mmol/L**	< 2.8 or > 6.0 mmol/L	Ch. 3, 16, 27
Chloride (Cl^-)	Serum / Plasma	**98–107 mmol/L**	< 80 or > 115 mmol/L	Ch. 3
Bicarbonate (HCO_3^- / Total CO_2)	Serum / Venous	**22–26 mmol/L**	< 15 or > 40 mmol/L	Ch. 3, 15, 27
Calcium, Total (Ca^{2+})	Serum	**2.15–2.55 mmol/L**	< 1.75 or > 3.25 mmol/L	Ch. 3, 23, 27
Calcium, Ionized	Whole Blood	**1.15–1.30 mmol/L**	< 0.80 or > 1.60 mmol/L	Ch. 3, 20, 23
Magnesium (Mg^{2+})	Serum	**0.70–1.05 mmol/L**	< 0.50 or > 2.00 mmol/L	Ch. 3, 16
Phosphate (PO_4^{3-})	Serum	**0.80–1.45 mmol/L**	< 0.32 mmol/L	Ch. 3, 27
Glucose (Fasting)	Plasma	**4.0–6.0 mmol/L**	< 2.8 or > 25.0 mmol/L	Ch. 22
HbA1c	Whole Blood	**4.5%–5.9% (Target ≤ 7.0%)**	—	Ch. 22
Urea (BUN equivalent)	Serum / Plasma	**2.5–7.1 mmol/L**	> 35.0 mmol/L	Ch. 27
Creatinine	Serum / Plasma	**50–110 µmol/L**	> 400 µmol/L (acute)	Ch. 27
eGFR	Calculated	**≥ 90 mL/min/1.73 m²**	< 15 mL/min/1.73 m² (G5)	Ch. 27
Lactate (Arterial / Venous)	Plasma	**0.5–2.0 mmol/L**	≥ 4.0 mmol/L (septic shock)	Ch. 4, 6
Serum Osmolality	Serum	**275–295 mOsm/kg**	< 250 or > 325 mOsm/kg	Ch. 3, 22, 30
Hemoglobin (Hb)	Whole Blood	**120–160 g/L (F) / 135–175 g/L (M)**	< 70 g/L (transfusion threshold)	Ch. 20, 24
Hematocrit (Hct)	Whole Blood	**0.36–0.46 L/L (F) / 0.40–0.50 L/L (M)**	< 0.21 L/L	Ch. 20
White Blood Cell Count (WBC)	Whole Blood	**4.0–11.0 × 10^9/L**	< 1.5 or > 30.0 × 10^9/L	Ch. 4, 9, 20
Absolute Neutrophil Count (ANC)	Whole Blood	**2.0–7.5 × 10^9/L**	< 0.5 × 10^9/L (febrile neutropenia)	Ch. 9, 20
Platelets	Whole Blood	**150–400 × 10^9/L**	< 20 × 10^9/L or > 1,000 × 10^9/L	Ch. 20, 26
INR (International Normalized Ratio)	Citrated Plasma	**0.9–1.2 (Warfarin target 2.0–3.0)**	> 4.5 (major bleeding risk)	Ch. 16, 19, 20
aPTT	Citrated Plasma	**25–35 seconds**	> 100 seconds	Ch. 15, 19, 20
D-Dimer	Plasma	**< 500 µg/L FEU**	Age-adjusted cutoff over 50 yr	Ch. 15, 19

Analyte	Specimen	Adult SI Reference Interval	Critical / Escalation Threshold	Primary Chapters
Troponin I / T (High-Sensitivity)	Plasma	**< 99th percentile URL (ng/L)**	Dynamic rise/fall (ACS)	Ch. 17
BNP / NT-proBNP	Plasma	**BNP < 100 pg/mL; NT-proBNP < 300 pg/mL**	Acute decompensated HF	Ch. 18
Total Bilirubin	Serum	**3–21 µmol/L**	> 250 µmol/L	Ch. 20, 26
ALT / AST	Serum	**ALT 7–40 U/L; AST 10–40 U/L**	> 1,000 U/L (acute hepatic injury)	Ch. 26
Albumin	Serum	**35–50 g/L**	< 20 g/L	Ch. 24, 26, 27
Ammonia (NH_3)	Plasma	**15–45 µmol/L**	> 100 µmol/L (encephalopathy)	Ch. 26
Lipase	Serum	**10–140 U/L**	> 3 × ULN (acute pancreatitis)	Ch. 26
TSH (Thyroid-Stimulating Hormone)	Serum	**0.40–4.50 mIU/L**	< 0.01 or > 20.0 mIU/L	Ch. 23
Uric Acid (Urate)	Serum	**180–420 µmol/L (Target < 360 µmol/L)**	> 540 µmol/L	Ch. 34
Arterial pH	Arterial Blood	**7.35–7.45**	< 7.20 or > 7.60	Ch. 3, 15
$PaCO_2$	Arterial Blood	**35–45 mmHg**	< 20 or > 65 mmHg	Ch. 3, 12, 15
PaO_2	Arterial Blood	**80–100 mmHg**	< 60 mmHg (hypoxemic failure)	Ch. 12, 15

BACK MATTER — CUMULATIVE LEXICON *Appendix B*

B Cumulative Glossary of Medical-Surgical Terms (1651 Terms)

2SLGBTQI+: An umbrella term for Two-Spirit, lesbian, gay, bisexual, transgender, queer and intersex people and others who are sexually and gender diverse; "2S" is placed first in recognition that Two-Spirit people formed the first of these communities. *(Ch. 2)*

4AT: a brief delirium screening test, usually taking less than two minutes, that looks at alertness, orientation, attention and acute change. *(Ch. 8)*

5-alpha reductase inhibitor (5-ARI): a drug that shrinks the prostate over months and lowers the PSA level by about half. *(Ch. 28)*

A1C: the percentage of hemoglobin with glucose attached, reflecting average glucose over the previous 8 to 12 weeks *(Ch. 22)*

abdominal aortic aneurysm (AAA): a weak area in the wall of the abdominal aorta that balloons outward. *(Ch. 19)*

abdominoperineal resection: surgery that removes the lower rectum and anal sphincter for a tumour near the anus, leaving a permanent colostomy. *(Ch. 25)*

abnormal extension: A motor response in which the arm straightens at the elbow in response to a stimulus; it ranks lower on the GCS than abnormal flexion. *(Ch. 30)*

abnormal flexion: A slow, stereotyped motor response with the arm bent across the chest, forearm turning, thumb clenched and leg extended; a sign of severe brain dysfunction. *(Ch. 30)*

abnormal uterine bleeding: Uterine bleeding that differs from a person's usual menstrual pattern in amount, duration, frequency or regularity, or that occurs between periods. *(Ch. 29)*

abscess: A walled-off collection of pus in the skin or the tissue beneath it, treated mainly by incision and drainage. *(Ch. 35)*

absolute neutrophil count (ANC): The number of neutrophils per litre of blood, reported in × 10^9/L. *(Ch. 9)*

acanthosis nigricans: thick, velvety, darker skin in body folds such as the neck and armpits; a sign of insulin resistance *(Ch. 22)*

acidemia: A blood pH below the normal range. *(Ch. 3)*

acidosis: A process that adds acid or removes base, tending to lower pH. *(Ch. 3)*

acquired immunodeficiency syndrome (AIDS) / advanced HIV disease: the most advanced stage of HIV infection, defined for surveillance as a CD4 count below 200 cells/µL, a CD4 percentage below 14%, or an AIDS-defining opportunistic illness. *(Ch. 21)*

acral melanoma: A type of melanoma on the palms, soles or nails that is not linked to ultraviolet exposure; the most common type in people with darker skin. *(Ch. 35)*

acromegaly: a condition caused by excess growth hormone in adults, usually from a pituitary adenoma, with enlarged hands, feet and facial features. *(Ch. 23)*

action plan: A written, personalized guide that tells a person with heart failure which signs to watch for and what to do, often organized in green, yellow and red zones. *(Ch. 18)*

active offer: Making services in French visible and available from the first contact so that Francophone patients do not have to ask for them. *(Ch. 1)*

active surveillance: planned monitoring of a low-risk prostate cancer with PSA tests, examinations and biopsies, with treatment offered if the cancer changes. *(Ch. 28)*

acute angle-closure glaucoma: An eye emergency in which the drainage angle closes and intraocular pressure rises quickly, causing eye pain, headache, halos, blurred vision, nausea and vomiting. *(Ch. 36)*

acute aortic syndrome: A life-threatening injury to the wall of the aorta, such as aortic dissection, that causes sudden severe pain. *(Ch. 19)*

acute chest syndrome: a new lung infiltrate with fever or respiratory symptoms in a person with sickle cell disease; an emergency *(Ch. 20)*

acute cholecystitis: Inflammation of the gallbladder, usually because a stone is stuck in its neck; the pain persists for longer than biliary colic and is often accompanied by fever and right upper quadrant tenderness. *(Ch. 26)*

acute colonic pseudo-obstruction: marked widening of the colon without a mechanical blockage, usually in older, seriously ill or postoperative patients. *(Ch. 25)*

acute coronary syndrome (ACS): a sudden fall in blood flow to the heart muscle, usually from plaque rupture or erosion with thrombus; includes unstable angina, NSTEMI and STEMI. *(Ch. 17)*

acute decompensated heart failure (ADHF): Worsening of known heart failure that needs urgent treatment, usually in hospital. *(Ch. 18)*

acute exacerbation of COPD: A sudden flare-up in which symptoms such as breathlessness, sputum volume or sputum purulence get worse over a period of days, 14 days at most. *(Ch. 14)*

acute heart failure: A sudden or gradual change in heart failure symptoms and signs that calls for urgent treatment. *(Ch. 18)*

acute hemolytic transfusion reaction: rapid destruction of transfused red cells, most often from ABO incompatibility, causing fever, pain, hypotension and dark urine. *(Ch. 20)*

acute HIV infection: the first weeks after HIV enters the body, when the viral load is very high, the person is highly infectious and a flu-like illness may occur. *(Ch. 21)*

acute inflammation: A short-lived inflammatory response, dominated by neutrophils, that removes the cause of injury and then resolves. *(Ch. 4)*

acute kidney injury (AKI): a sudden fall in kidney function over hours to days, defined by KDIGO by a rise in creatinine or a fall in urine output *(Ch. 27)*

acute limb ischemia: sudden loss of blood flow to a limb that threatens its survival and needs emergency treatment. *(Ch. 19)*

acute liver failure (ALF): A sudden, severe loss of liver function in a person without cirrhosis, with an INR of 1.5 or higher and any degree of encephalopathy, arising within 26 weeks of the start of the illness. *(Ch. 26)*

acute pain: pain of recent onset, usually from injury, illness, surgery or trauma, that settles as the cause heals *(Ch. 5)*

acute pancreatitis: Acute inflammation of the pancreas, diagnosed when two of three features are present: typical pain, lipase or amylase at least three times the upper limit of normal, and typical imaging findings. *(Ch. 26)*

acute pulmonary edema: An emergency in which fluid floods the alveoli, causing severe breathlessness and hypoxemia. *(Ch. 18)*

acute respiratory distress syndrome: A sudden, widespread inflammatory injury to both lungs that causes noncardiogenic pulmonary edema and hypoxemic respiratory failure within 1 week of a trigger. *(Ch. 15)*

acute respiratory failure: Failure of the lungs to keep blood oxygen and carbon dioxide within safe limits, developing over minutes to days. *(Ch. 15)*

acute severe ulcerative colitis: A flare of UC with frequent bloody stools and signs of systemic illness that needs hospital admission and IV corticosteroids. *(Ch. 25)*

acute tubular injury: damage to the kidney tubule cells from prolonged low blood flow, sepsis or toxins; a common form of intrinsic AKI in hospital *(Ch. 27)*

adaptive immunity: the slower, antigen-specific part of the immune system, carried out by B cells and T cells, that develops memory after exposure. *(Ch. 21)*

Addison disease: primary adrenal insufficiency, in which the adrenal cortex is damaged, most often by autoimmune disease, so cortisol and usually aldosterone are low. *(Ch. 23)*

additional precautions: Infection control measures used on top of routine practices for certain organisms or clinical presentations; contact, droplet and airborne precautions. *(Ch. 4)*

adenoma: a type of polyp in the colon or rectum that can become cancer over time. *(Ch. 25)*

adhesions: bands of scar tissue inside the abdomen, usually after surgery or inflammation; the most common cause of small bowel obstruction. *(Ch. 25)*

adjuvant analgesic: a drug whose main use is not pain relief but which relieves some types of pain, especially neuropathic pain *(Ch. 5)*

adjuvant therapy: treatment given after surgery to destroy cancer cells that may remain. *(Ch. 9)*

adrenal cortex: the outer part of the adrenal gland, which makes the steroid hormones cortisol and aldosterone. *(Ch. 23)*

adrenal crisis: a life-threatening emergency in which cortisol supply cannot meet the body's needs, causing hypotension, volume depletion, vomiting and confusion; treated at once with parenteral hydrocortisone and isotonic saline. *(Ch. 23)*

adrenal insufficiency: a condition in which the adrenal glands do not supply enough cortisol, with or without enough aldosterone. *(Ch. 23)*

adrenal medulla: the inner part of the adrenal gland, which releases the catecholamines epinephrine and norepinephrine. *(Ch. 23)*

advance care planning: The ongoing process of reflecting on values and wishes for future care, sharing them with family and the care team, and choosing a substitute decision-maker. *(Ch. 32)*

advance care planning (ACP): A voluntary process in which a capable person confirms or chooses a substitute decision-maker and shares wishes, values and beliefs about future care; in Ontario it is not consent. *(Ch. 10)*

adverse event following immunization (AEFI): any unwanted or unexpected health effect that follows a vaccine, whether or not the vaccine caused it. *(Ch. 21)*

afterload: the resistance the ventricle must pump against to eject blood. *(Ch. 6)*

age-adjusted D-dimer cut-off: A D-dimer threshold for patients over 50, calculated as age × 10 mcg/L, that reduces false-positive results in older adults. *(Ch. 15)*

age-related macular degeneration (AMD): Age-related disease of the macula that causes loss of central vision; it occurs in a dry (atrophic) form and a wet (neovascular) form. *(Ch. 36)*

ageism: stereotyping, prejudice or discrimination against people because of their age. *(Ch. 8)*

agent: Under PHIPA, a person, such as a nurse employed by a hospital, who handles personal health information on behalf of a health information custodian. *(Ch. 1)*

agranulocytosis: A severe drop in neutrophils, a rare but life-threatening adverse effect of antithyroid drugs. *(Ch. 23)*

air leak: Air entering a chest drainage system from the lung or through a loose connection, seen as bubbling in the water seal chamber. *(Ch. 15)*

air trapping: Air left behind in the lungs at the end of each breath because narrowed or unsupported small airways close early during exhalation. *(Ch. 14)*

airborne infection isolation room (AIIR): A single room designed and ventilated (negative pressure) to keep airborne organisms from spreading beyond it. *(Ch. 4)*

airborne precautions: Precautions for organisms carried on small particles that stay suspended in the air; they require a negative pressure room with the door closed and a fit-tested N95 respirator. *(Ch. 4)*

airway hyperresponsiveness: A tendency of the airways to narrow quickly and strongly in response to stimuli that barely affect other people. *(Ch. 14)*

airway resistance: how much the airways oppose airflow; narrowing from spasm, swelling or secretions raises it. *(Ch. 12)*

alarm fatigue: Desensitization of clinicians exposed to many false or non-actionable alarms, leading to slower or missed responses. *(Ch. 16)*

alarm features: symptoms such as dysphagia, unplanned weight loss, bleeding, anemia or persistent vomiting that suggest a serious cause and call for prompt assessment. *(Ch. 24)*

albumin: A plasma protein, also given as a colloid solution made from pooled human plasma, that raises plasma oncotic pressure and holds fluid in the blood vessels. *(Ch. 3)*

albuminuria: albumin in the urine, an early marker of kidney damage; classified by KDIGO as A1, A2 or A3 *(Ch. 27)*

alcohol withdrawal: the signs and symptoms of an overexcited nervous system that follow stopping or sharply reducing heavy, prolonged alcohol use. *(Ch. 11)*

alcohol-associated hepatitis: The acute inflammatory stage of alcohol-related liver disease, typically with new jaundice in a person who has been drinking heavily. *(Ch. 26)*

alcohol-related liver disease (ALD): Liver injury caused by drinking alcohol over time, ranging from fatty liver through alcohol-associated hepatitis and fibrosis to cirrhosis and liver cancer. *(Ch. 26)*

alcoholic hallucinosis: hallucinations during alcohol withdrawal in a person who otherwise remains oriented. *(Ch. 11)*

aldosterone: A hormone from the adrenal cortex that causes the kidneys to keep sodium, and with it water. *(Ch. 3)*

alkalemia: A blood pH above the normal range. *(Ch. 3)*

alkalosis: A process that removes acid or adds base, tending to raise pH. *(Ch. 3)*

allergy: a hypersensitivity reaction to a substance that is harmless to most people, such as a food, pollen or drug. *(Ch. 21)*

allergy (drug): an immune reaction to a drug, such as hives, swelling, wheezing or a severe skin reaction. *(Ch. 4)*

allodynia: pain from a stimulus that does not normally cause pain, such as light touch *(Ch. 5)*

alpha-1 antitrypsin deficiency: An inherited lack of a protein that protects the lungs from damage; a genetic risk factor for COPD. *(Ch. 14)*

alpha-blocker: a drug that relaxes smooth muscle in the prostate and bladder neck, improving urine flow; can cause dizziness and low blood pressure. *(Ch. 28)*

alternate level of care (ALC): A designation for a patient who remains in a hospital bed but no longer needs acute care and is waiting for a more suitable setting. *(Ch. 1)*

alveolar–capillary membrane: the thin barrier between alveolar air and capillary blood across which oxygen and carbon dioxide diffuse. *(Ch. 12)*

alveoli: the tiny air sacs at the ends of the smallest airways, where gas exchange takes place. *(Ch. 12)*

ambulatory blood pressure monitoring (ABPM): Blood pressure measured automatically every 20 to 30 minutes over a day and night by a device the person wears. *(Ch. 19)*

ambulatory surgery: Surgery after which the patient goes home on the same day; also called day surgery or same-day surgery. *(Ch. 7)*

American Sign Language (ASL): A full signed language with its own grammar, used by many Deaf people in English-speaking Canada; recognized in the Accessible Canada Act as one of the primary languages of communication for deaf persons in Canada. *(Ch. 36)*

amputation: The removal of all or part of a limb. *(Ch. 33)*

amyotrophic lateral sclerosis (ALS): A progressive disease in which the motor nerve cells of the brain and spinal cord degenerate, causing weakness, muscle wasting and, eventually, respiratory failure. *(Ch. 32)*

anaphylaxis: a severe, potentially life-threatening allergic reaction with sudden onset, usually involving two or more body systems. *(Ch. 6)*

anastomosis: a surgical join between two ends of bowel after a segment is removed. *(Ch. 25)*

anastomotic leak: escape of stomach or intestinal contents through a surgical staple or suture line. *(Ch. 24)*

androgen deprivation therapy (ADT): treatment that lowers testosterone to slow the growth of prostate cancer. *(Ch. 28)*

anemia: a hemoglobin below the reference range for the person's age and sex; a sign with an underlying cause *(Ch. 20)*

anemia of inflammation: anemia caused by inflammatory signals that block iron absorption and trap iron in storage cells *(Ch. 20)*

anesthesia assistant: A formally designated team member with specific training in anesthesia assistance who carries out tasks approved by the department of anesthesia and the facility. *(Ch. 7)*

anginal equivalent: a symptom other than chest pain, such as breathlessness or unusual fatigue on exertion, that reflects myocardial ischemia. *(Ch. 17)*

angioedema: Swelling of the lips, tongue, face or throat; an emergency that can follow ACE inhibitors, ARBs or an ARNI. *(Ch. 18)*

angiotensin receptor–neprilysin inhibitor (ARNI): A drug combining neprilysin inhibition with angiotensin II receptor blockade; sacubitril/valsartan. *(Ch. 18)*

anion gap: A calculated value (sodium minus chloride and bicarbonate, with or without potassium) that estimates unmeasured anions; a high gap suggests added acid. *(Ch. 3)*

ankle-brachial index (ABI): the ratio of ankle to arm systolic pressure; the CCS states that a value below 0.9 suggests PAD. *(Ch. 19)*

anogenital warts: Skin growths in the genital or anal area caused mainly by HPV types 6 and 11. *(Ch. 29)*

anti-Black racism: The discrimination, stereotyping and prejudice that people of African descent face, built into the policies, practices and institutions of Canadian society and often unseen because it is so normal. *(Ch. 2)*

anti-CCP antibodies: Antibodies to cyclic citrullinated peptides; a blood test that is more specific for rheumatoid arthritis than rheumatoid factor, although a negative result does not rule the disease out. *(Ch. 34)*

anti-racism: Active practice that names racism, including racism built into systems, and works to reduce the power differences that disadvantage racialized people. *(Ch. 2)*

anti-VEGF therapy: Medicines that block vascular endothelial growth factor, injected into the eye to treat wet AMD and diabetic eye disease. *(Ch. 36)*

antibiotic-resistant organism (ARO): a microorganism that has changed so that one or more antibiotics that once treated it no longer work well against it. *(Ch. 4)*

antibody: a protein (immunoglobulin) made by plasma cells that binds one specific antigen. *(Ch. 21)*

anticholinergic burden: The cumulative effect of all the drugs a person takes that have anticholinergic properties. *(Ch. 8)*

anticipatory grief: Grief that begins before a death, as the patient and family face coming losses. *(Ch. 10)*

anticipatory medications: Drugs ordered in advance for expected end-of-life symptoms so that relief can be given at any hour. *(Ch. 10)*

anticoagulant: a drug that slows clot formation and stops existing clots from growing. *(Ch. 19)*

antidiuretic hormone (ADH): A hormone, also called vasopressin, released from the posterior pituitary when osmolality rises or blood volume falls; it makes the kidneys return more water to the blood. *(Ch. 3)*

antifibrotic: A drug, such as nintedanib or pirfenidone, that slows the loss of lung function in pulmonary fibrosis without reversing scarring. *(Ch. 14)*

antigen: any molecule that the immune system can recognize as a target and respond to. *(Ch. 21)*

antimicrobial stewardship: coordinated actions to use antimicrobials only when needed, with the right drug, dose, route and duration, to improve outcomes and limit harm and resistance. *(Ch. 4)*

antiplatelet therapy: Medicines, such as ASA or clopidogrel, that keep platelets from clumping to form clots. *(Ch. 31)*

antiretroviral therapy (ART): a combination of drugs from different classes that stops HIV from multiplying. *(Ch. 21)*

antiseizure medication: A medicine used to prevent or stop seizures, such as levetiracetam, phenytoin or lacosamide. *(Ch. 30)*

antiviral: a drug that stops a virus from multiplying, such as oseltamivir for influenza or nirmatrelvir–ritonavir for COVID-19. *(Ch. 13)*

aortic dissection: A tear in the inner lining of the aorta that lets blood track between the layers of its wall. *(Ch. 19)*

aortic stenosis: Narrowing of the aortic valve that obstructs blood flow out of the left ventricle. *(Ch. 18)*

aphasia: A disorder of language from damage to the brain's language areas that can affect speaking, understanding, reading and writing. *(Ch. 30)*

aplastic anemia: failure of the bone marrow to produce enough red cells, white cells and platelets *(Ch. 20)*

apnea: A pause in breathing. *(Ch. 10)*

apolipoprotein B (ApoB): the protein on each atherogenic lipoprotein particle; its level, in g/L, reflects the number of particles that can enter the artery wall. *(Ch. 17)*

apoptosis: orderly, programmed cell death that removes damaged or unneeded cells. *(Ch. 9)*

appendicitis: Inflammation of the appendix, usually after its opening is blocked. *(Ch. 25)*

appendicolith: A hard stone of stool in the appendix that raises the risk of perforation and of failure of antibiotic treatment. *(Ch. 25)*

aqueous humour: The clear fluid made by the ciliary processes that fills the front of the eye and drains through the drainage angle and the uveoscleral route. *(Ch. 36)*

areflexia: Absence of deep tendon reflexes. *(Ch. 32)*

arginine vasopressin deficiency (AVP-D): the current name for central diabetes insipidus, in which too little vasopressin is released, so large volumes of dilute urine are passed. *(Ch. 23)*

arginine vasopressin resistance (AVP-R): the current name for nephrogenic diabetes insipidus, in which the kidneys do not respond to vasopressin. *(Ch. 23)*

arterial blood gas (ABG): A test of arterial blood that measures pH, $PaCO_2$, PaO_2 and bicarbonate. *(Ch. 3)*

arteriovenous fistula (AV fistula): a surgical joining of an artery and a vein, usually in the arm, that creates a large, strong vein for hemodialysis needles. *(Ch. 27)*

arteriovenous graft (AV graft): a tube of synthetic or biological material that joins an artery to a vein and is used for hemodialysis needles. *(Ch. 27)*

arthritis: Inflammation of a joint; used as a general term for many conditions that affect joints and the tissues around them. *(Ch. 34)*

articular cartilage: The smooth, firm tissue covering the ends of bones in a synovial joint, which lets them glide and spreads the load. *(Ch. 34)*

artifact: A signal on an ECG or monitor that does not come from the heart's electrical activity, such as interference from movement or loose electrodes. *(Ch. 16)*

artificial nutrition and hydration: Nutrition and fluids given by tube or by the intravenous or subcutaneous route; a medical treatment that requires a values-based decision and consent. *(Ch. 10)*

ASA Physical Status classification: A six-class system used by anesthesiologists to describe a patient's overall health before anesthesia, with "E" added for emergency surgery. *(Ch. 7)*

ascending paralysis: Weakness that starts in the legs and spreads upward to the arms and the muscles of breathing, swallowing and the face. *(Ch. 32)*

ascites: A build-up of fluid in the peritoneal cavity, most often caused by portal hypertension in cirrhosis. *(Ch. 26)*

aspiration: the passage of material from the mouth, throat or stomach into the airways. *(Ch. 13)*

aspiration pneumonia: a lung infection that follows the breathing in of mouth and throat secretions that carry bacteria, usually in a person with dysphagia. *(Ch. 13)*

aspiration pneumonitis: a chemical lung injury caused by breathing in a large volume of stomach contents, usually in a person with reduced consciousness. *(Ch. 13)*

asterixis: A flapping movement of the outstretched hands with the wrists bent back, caused by brief loss of muscle tone; a sign of hepatic encephalopathy. *(Ch. 26)*

asthma: A chronic, usually inflammatory airway disease with variable symptoms and variable airflow limitation. *(Ch. 14)*

asthma control: How well treatment keeps asthma symptoms and exacerbations away, judged against set criteria. *(Ch. 14)*

asthma exacerbation: A flare in which asthma symptoms and lung function worsen beyond the person's usual variation. *(Ch. 14)*

asymptomatic bacteriuria: Bacteria in the urine without symptoms of urinary tract infection; screened for and treated in pregnancy but not in most other adults. *(Ch. 29)*

asymptomatic bacteriuria (ASB): Bacteria in the urine at a significant count in a person with no signs or symptoms of urinary tract infection; usually not screened for or treated. *(Ch. 28)*

asystole: The absence of electrical activity in the ventricles, seen as a flat line; a non-shockable arrest rhythm. *(Ch. 16)*

atelectasis: collapse of the small air sacs (alveoli) in part of the lung, common after surgery when breathing is shallow. *(Ch. 7)*

atherosclerosis: a chronic inflammatory disease of the artery wall in which lipids, immune cells and fibrous tissue build up beneath the lining to form plaque. *(Ch. 17)*

atrial fibrillation (AF): A dysrhythmia in which disorganized atrial activity produces an irregularly irregular ventricular rhythm with no clear P waves. *(Ch. 16)*

atrial flutter: A dysrhythmia caused by an organized loop of atrial activity that produces regular sawtooth flutter waves. *(Ch. 16)*

atrioventricular (AV) node: Conduction tissue low in the right atrium that delays the impulse before it reaches the ventricles; with the bundle of His, the normal route from atria to ventricles. *(Ch. 16)*

atypical bacteria: bacteria such as Legionella that cause pneumonia but need special tests, such as urine antigen tests or selective cultures, to detect. *(Ch. 13)*

audiogram: A chart of the softest sounds a person can hear in each ear across a range of pitches, produced by a hearing test. *(Ch. 36)*

AUDIT-C: a short alcohol screening tool built from the consumption questions of the Alcohol Use Disorders Identification Test. *(Ch. 11)*

authorizing mechanism: A legal means, such as an order, a directive or delegation, that gives a nurse authority to perform a controlled act or other activity the nurse cannot start alone. *(Ch. 1)*

autoimmune disease: A disease in which the immune system attacks the body's own tissues. *(Ch. 34)*

autoimmunity: an immune response against the body's own tissues that results from a breakdown of self-tolerance. *(Ch. 21)*

automated external defibrillator (AED): A portable device that analyzes the heart rhythm, decides whether a shock is needed and guides the rescuer with prompts. *(Ch. 16)*

automated office blood pressure (AOBP): Several readings taken and averaged by a validated automated upper-arm device in a health care setting. *(Ch. 19)*

autonomic dysfunction: Damage to the nerves that control heart rate, blood pressure, bowel and bladder, causing swings in vital signs and other problems. *(Ch. 32)*

autonomic dysreflexia: A sudden, dangerous rise in blood pressure, triggered by a stimulus below a spinal cord injury, usually at T6 or above. *(Ch. 32)*

autonomic neuropathy: damage to the nerves that control internal organs, causing problems such as orthostatic hypotension, gastroparesis, bladder dysfunction and sweating changes. *(Ch. 22)*

autoregulation: The ability of cerebral blood vessels to widen or narrow to keep brain blood flow fairly steady when blood pressure changes. *(Ch. 30)*

axillary lymph node dissection: Surgery that removes lymph nodes from the armpit, usually when breast cancer has spread to them. *(Ch. 29)*

axis: A chain of control in which the hypothalamus and pituitary stimulate a target gland, such as the thyroid or adrenal cortex. *(Ch. 23)*

B symptoms: unexplained fever above 38 °C, drenching night sweats and unexplained loss of more than 10% of body weight in the 6 months before diagnosis. *(Ch. 20)*

back slab: A plaster or fibreglass splint moulded along one side of a limb and held on with a bandage, leaving room for swelling. *(Ch. 33)*

bacterial meningitis: A bacterial infection of the meninges that cover the brain and spinal cord; a medical emergency. *(Ch. 30)*

balanced solution: An isotonic crystalloid, such as Plasma-Lyte A, whose electrolyte content is closer to plasma than that of 0.9% sodium chloride. *(Ch. 3)*

bariatric surgery: surgery on the stomach, intestine or both to support long-term weight loss and improve obesity-related disease. *(Ch. 24)*

Barrett esophagus: a precancerous change in the lining of the lower esophagus, linked with long-term reflux, that raises the risk of esophageal cancer. *(Ch. 24)*

basal cell carcinoma: The most common skin cancer, starting in the basal cells of the epidermis; it usually grows slowly and rarely spreads. *(Ch. 35)*

basal insulin: background insulin that controls glucose between meals and overnight *(Ch. 22)*

basal-bolus insulin: an insulin plan that combines background (basal) insulin, mealtime (bolus) insulin and correction insulin for high readings. *(Ch. 22)*

Beck's triad: Low blood pressure, distended neck veins and muffled heart sounds, a classic but often incomplete sign of cardiac tamponade. *(Ch. 18)*

Beers Criteria: The American Geriatrics Society's list of medications to avoid or use with caution in adults aged 65 and older, last updated in 2023. *(Ch. 8)*

benign paroxysmal positional vertigo (BPPV): An inner ear disorder causing brief spells of vertigo, usually a minute or less, triggered by changes in head position. *(Ch. 36)*

benign prostatic hyperplasia (BPH): non-cancerous enlargement of the prostate that can narrow the urethra. *(Ch. 28)*

bereavement: The state of having lost someone through death. *(Ch. 10)*

best possible medication history: A medication history built from a structured interview with the patient or family and at least one other reliable source, covering all prescribed and non-prescribed medications. *(Ch. 1)*

bilateral salpingo-oophorectomy: Surgical removal of both ovaries and both fallopian tubes. *(Ch. 29)*

bilevel positive airway pressure: A form of NIV that gives a higher pressure on inspiration and a lower pressure on expiration, resting the breathing muscles and helping clear CO2. *(Ch. 15)*

biliary colic: Pain, usually lasting about 30 minutes to 4 hours, caused when a gallstone briefly blocks the cystic duct; felt in the right upper quadrant or epigastrium, often after a meal. *(Ch. 26)*

bilirubin: A yellow pigment made when old red blood cells break down; the liver conjugates it and secretes it into bile. *(Ch. 26)*

biofilm: A complex community of bacteria and fungi held together on a wound in a slimy coating made of sugars and proteins; it delays healing and cannot be detected by standard culture. *(Ch. 35)*

biologic: An injected antibody medicine that blocks a specific step in airway inflammation, used for some people with severe asthma. *(Ch. 14)*

biologic therapy: A drug made from living cells, such as an anti-TNF agent, given by infusion or injection to block a specific part of the immune response. *(Ch. 25)*

bioprosthetic valve: A replacement heart valve made from animal tissue; it does not need lifelong anticoagulation but wears out over time. *(Ch. 18)*

biopsy: Removal of a tissue sample for examination by a pathologist; the only test that confirms breast cancer. *(Ch. 29)*

biosimilar: a lower-cost insulin highly similar to an original brand-name insulin *(Ch. 22)*

biphasic reaction: a return of anaphylaxis symptoms after the first reaction has settled, without new exposure to the trigger. *(Ch. 6)*

bitemporal visual field loss: loss of the outer (temporal) visual fields of both eyes, caused by pressure on the optic chiasm. *(Ch. 23)*

bladder diary: A record of fluid intake, voids, urgency and leaks kept over several days to assess bladder problems. *(Ch. 28)*

bladder scanner: A portable ultrasound device that estimates the volume of urine in the bladder. *(Ch. 28)*

bladder training: A schedule of voiding at set times, with intervals lengthened gradually, combined with urge-suppression techniques. *(Ch. 28)*

blood component: a part of donated blood separated after collection, such as red cells, platelets, plasma or cryoprecipitate. *(Ch. 20)*

blood culture: a blood sample placed in culture bottles to detect and identify bacteria or fungi in the bloodstream, collected before the first antibiotic dose when possible. *(Ch. 13)*

blood–brain barrier: Tightly joined cells that limit which substances pass from the blood into brain tissue. *(Ch. 30)*

bolus: A soft, cohesive mass of chewed food or fluid that the tongue shapes and moves to the back of the mouth for swallowing. *(Ch. 24)*

bolus (prandial) insulin: insulin given with meals to cover the rise in glucose from food *(Ch. 22)*

bone mineral density (BMD): The amount of mineral in a given area of bone, measured with dual-energy X-ray absorptiometry (DXA). *(Ch. 33)*

bowel obstruction: any problem that stops intestinal contents from moving forward, either a mechanical blockage or a loss of bowel movement (ileus). *(Ch. 25)*

bowel regimen: a scheduled laxative plan started with regular opioids to prevent constipation. *(Ch. 5)*

brachytherapy: radiation therapy in which a sealed radioactive source is placed inside or next to a tumour. *(Ch. 9)*

bradykinesia: Slowness of movement, seen as small steps, a soft voice and small handwriting. *(Ch. 32)*

brainstem: The midbrain, pons and medulla, which link the brain to the spinal cord and control breathing, heart rate, many reflexes and arousal. *(Ch. 30)*

breast-conserving surgery: Surgery that takes out a breast tumour with a rim of healthy tissue and keeps the rest of the breast; usually followed by radiation. *(Ch. 29)*

brief intervention: a short, structured conversation, based on motivational interviewing, that helps a person consider their substance use and choose a change. *(Ch. 11)*

briefing: The checklist phase completed before anesthesia begins. *(Ch. 7)*

Bristol Stool Form Scale: A seven-type picture chart that describes stool form, from separate hard lumps (type 1) to entirely liquid stool (type 7), and gives a rough guide to transit time. *(Ch. 25)*

bronchiectasis: Permanent widening of the bronchi, seen on CT, with chronic symptoms and recurrent exacerbations. *(Ch. 14)*

bronchoconstriction: Tightening of the smooth muscle around the airways, which narrows them. *(Ch. 14)*

bruit: the sound of blood flow through a fistula or graft heard with a stethoscope; normally low-pitched and continuous. *(Ch. 27)*

buffer: A chemical system, such as bicarbonate and carbonic acid, that takes up or releases hydrogen ions to limit changes in pH. *(Ch. 3)*

buprenorphine: a partial mu-opioid agonist used as a first-line opioid agonist treatment, often combined with naloxone or given as an extended-release injection. *(Ch. 5)*

burn: Damage to the skin or deeper tissues caused by heat, chemicals, electricity, radiation, friction or extreme cold. *(Ch. 35)*

C-reactive protein (CRP): An acute-phase protein whose blood level rises with inflammation of any cause; it is not specific to infection. *(Ch. 4)*

cachexia: A syndrome of continuing skeletal muscle loss (with or without loss of fat) that usual nutritional support cannot fully reverse and that steadily worsens function. *(Ch. 10)*

Cairo–Bishop criteria: A widely used set of laboratory and clinical criteria that define tumour lysis syndrome. *(Ch. 9)*

Calls to Action: The 94 specific steps issued by the Truth and Reconciliation Commission of Canada in 2015 to redress the legacy of residential schools and advance reconciliation; Calls 18 to 24 address health. *(Ch. 2)*

Canada Health Act: The federal law that sets the criteria and conditions provincial and territorial health insurance plans must meet to receive full federal cash contributions for insured health services. *(Ch. 1)*

Canadian Nosocomial Infection Surveillance Program (CNISP): the Public Health Agency of Canada's surveillance program, with sentinel hospitals, for healthcare-associated infections and antimicrobial resistance. *(Ch. 4)*

Canadian Nutrition Screening Tool (CNST): A two-question screen asking about unintended weight loss over the last six months and eating less than usual for over a week; a yes to both shows nutrition risk. *(Ch. 24)*

Canadian Problem Checklist: A screening checklist of emotional, practical and physical concerns used with the ESAS-r. *(Ch. 9)*

Canadian Triage and Acuity Scale (CTAS): Canada's five-level emergency department triage scale, maintained by a national committee of CAEP and NENA. *(Ch. 6)*

canalith repositioning manoeuvre: A series of head and body movements, such as the Epley manoeuvre, done by a trained clinician to treat BPPV. *(Ch. 36)*

cancer-related fatigue: A distressing, persistent sense of physical, emotional or mental exhaustion, out of proportion to activity and not relieved by rest. *(Ch. 9)*

cannabinoid hyperemesis syndrome (CHS): repeated episodes of severe nausea, vomiting and abdominal pain in people with heavy long-term cannabis use, often eased by hot showers and resolved by stopping cannabis. *(Ch. 11)*

Cannabis Act: the federal law under which non-medical cannabis has been legal and regulated in Canada since October 17, 2018. *(Ch. 11)*

capacity: The ability to understand information relevant to a specific treatment decision and to appreciate the reasonably foreseeable consequences of deciding or not deciding; it is presumed and treatment-specific, and it can change over time. *(Ch. 1)*

capnography: continuous measurement of exhaled carbon dioxide, which detects hypoventilation directly. *(Ch. 5)*

carbapenemase-producing organism (CPO): a bacterium that makes enzymes that break down carbapenem antibiotics, leaving few effective drugs; carbapenemase-producing Enterobacterales (CPE) are the main group. *(Ch. 4)*

carbon monoxide poisoning: Harm caused when inhaled carbon monoxide binds to hemoglobin and forms carboxyhemoglobin, which cannot carry oxygen; pulse oximetry can read falsely normal. *(Ch. 35)*

carcinogen: an agent, such as a chemical, radiation or a virus, that can damage DNA and cause cancer. *(Ch. 9)*

carcinogenesis: the multistep process by which a normal cell becomes a cancer cell. *(Ch. 9)*

cardiac amyloidosis: A restrictive cardiomyopathy in which misfolded proteins, often transthyretin, deposit in the heart muscle and stiffen it. *(Ch. 18)*

cardiac output: the volume of blood the heart pumps each minute; heart rate × stroke volume. *(Ch. 6)*

cardiac rehabilitation: A structured program of assessment, exercise, education and psychosocial support after a heart event or heart surgery. *(Ch. 17)*

cardiac resynchronization therapy (CRT): Pacing of both ventricles so they contract together. *(Ch. 18)*

cardiac tamponade: fluid or blood in the pericardial sac that compresses the heart and prevents it from filling. *(Ch. 6)*

cardiogenic shock: Shock caused by failure of the heart as a pump. *(Ch. 6)*

cardiomyopathy: A disease of the heart muscle itself that is not explained by coronary disease, hypertension or valve disease alone. *(Ch. 18)*

Care Coordination Service: Ontario's provincial service that gives information about MAID and other options at the end of life and connects people, including those who refer themselves, with physicians and NPs who provide MAID. *(Ch. 10)*

caregiver: A family member or friend who provides unpaid care and support to a person with an illness or disability. *(Ch. 32)*

caregiver strain: The physical, emotional and financial toll that caring for a family member or friend can take on the caregiver. *(Ch. 8)*

carotid bodies: small clusters of sensing cells beside the carotid arteries that respond to low arterial oxygen and to acidity. *(Ch. 12)*

cast: A rigid shell of plaster or fibreglass that wraps around a limb to hold a fracture still. *(Ch. 33)*

cataract: Clouding of the lens of the eye, most often with age. *(Ch. 36)*

catheter-associated urinary tract infection (CAUTI): A urinary tract infection in a person who has, or recently had, a urinary catheter. *(Ch. 28)*

CD4 T cell: a helper T cell that directs the immune response by releasing cytokines; the cell HIV infects and depletes. *(Ch. 21)*

cellulitis: A spreading infection of the skin and the tissue just beneath it, causing warmth, swelling, tenderness and a spreading change in colour. *(Ch. 35)*

central cyanosis: a bluish or greyish colour of the tongue, lips and oral lining that signals low arterial oxygen. *(Ch. 12)*

central nervous system (CNS): The brain and spinal cord. *(Ch. 30)*

central sensitization: increased responsiveness of pain neurons in the spinal cord and brain to normal or weak input *(Ch. 5)*

central venous access device: An IV catheter whose tip lies in a large central vein, such as a peripherally inserted central catheter (PICC), used for concentrated solutions such as most parenteral nutrition. *(Ch. 24)*

central venous catheter for dialysis: a large catheter in a central vein, usually in the neck, used for hemodialysis and reserved for dialysis staff. *(Ch. 27)*

cerebellum: The part of the brain at the back, below the cerebrum, that coordinates movement and learned motor skills. *(Ch. 30)*

cerebral amyloid angiopathy: A condition in which a protein called beta-amyloid builds up in the walls of small blood vessels in the outer brain and its coverings; a leading cause of bleeds in the outer lobes of the brain in older adults. *(Ch. 31)*

cerebral aneurysm: A weak, bulging area in the wall of a brain artery that can rupture and bleed. *(Ch. 31)*

cerebral edema: Swelling of brain tissue, for example around a tumour or after an injury. *(Ch. 30)*

cerebral perfusion pressure: The pressure that drives blood into the brain; mean arterial pressure minus intracranial pressure. *(Ch. 30)*

cerebrospinal fluid (CSF): The clear fluid made mainly in the choroid plexus of the ventricles that cushions the brain and spinal cord and carries away waste. *(Ch. 30)*

cerebrospinal fluid (CSF) leak: escape of the fluid around the brain, seen after transsphenoidal surgery as clear, watery nasal drainage or salty fluid in the throat. *(Ch. 23)*

cerebrum: The main part of the forebrain, the largest part of the brain, made of two hemispheres and four lobes; it controls conscious thought, memory, language and voluntary movement. *(Ch. 30)*

cerumen: Earwax, made by glands in the outer ear canal to protect and lubricate the canal. *(Ch. 36)*

cerumen impaction: A build-up of earwax that blocks the ear canal or causes symptoms such as fullness, muffled hearing, tinnitus or ear pain. *(Ch. 36)*

CHADS-65: The Canadian Cardiovascular Society algorithm that recommends oral anticoagulation for people with AF who are 65 or older or who have any CHADS2 risk factor. *(Ch. 16)*

chain of infection: A model of the six links needed for infection to spread (agent, reservoir, portal of exit, mode of transmission, portal of entry, susceptible host); breaking any link stops transmission. *(Ch. 4)*

Charcot triad: Fever, jaundice and abdominal pain; a highly specific but insensitive combination of signs of acute cholangitis. *(Ch. 26)*

Charles Bonnet syndrome: Seeing images of people, landscapes or patterns that are not there, after significant vision loss; it is often mistaken for dementia or a mental health problem. *(Ch. 36)*

chemical eye injury: Damage to the eye from a chemical splash; alkali injuries are generally more harmful than acid injuries. *(Ch. 36)*

chemical restraint: A medication given to control behaviour rather than to treat a diagnosed condition. *(Ch. 8)*

chemotherapy: treatment with cytotoxic drugs that kill cancer cells or slow their growth, along with other rapidly dividing cells. *(Ch. 9)*

chest physiotherapy: External chest wall techniques (percussion, vibration and postural drainage) used to help move secretions. *(Ch. 12)*

chest tube: A flexible tube placed between the ribs into the pleural space to drain air, blood or fluid and let the lung re-expand; also called an intercostal chest drain. *(Ch. 15)*

Cheyne-Stokes respiration: A cyclic breathing pattern of deepening and then shallower breaths followed by a pause. *(Ch. 10)*

Cheyne–Stokes breathing: a repeating cycle of breaths that deepen, then fade, followed by a pause in breathing. *(Ch. 12)*

chlamydia: A sexually transmitted infection caused by Chlamydia trachomatis; the sexually transmitted infection reported most often in Canada. *(Ch. 29)*

cholangitis: Infection of the bile ducts behind a blockage, most often a stone; severe cases cause organ dysfunction and need urgent drainage. *(Ch. 26)*

choledocholithiasis: A stone in the common bile duct. *(Ch. 26)*

cholelithiasis: Stones in the biliary tract, most often in the gallbladder. *(Ch. 26)*

cholinergic crisis: Severe weakness, with excess secretions and other cholinergic effects, caused by too much cholinesterase inhibitor. *(Ch. 32)*

chosen family: People a person chooses as family, such as close friends or partners, who may provide support in place of or alongside relatives by birth. *(Ch. 2)*

chosen name: The name a person uses, which may differ from the name on a health card or other legal record. *(Ch. 2)*

chronic bronchitis: Long-standing airway inflammation with thickened airway walls, excess mucus and a cough that brings up sputum on most days. *(Ch. 14)*

chronic inflammation: Inflammation that persists because the cause is not removed or the response fails to switch off, with ongoing tissue damage and scarring. *(Ch. 4)*

chronic kidney disease (CKD): an abnormality of kidney structure or function lasting more than three months with implications for health, classified by cause, GFR category and albuminuria category *(Ch. 27)*

chronic limb-threatening ischemia (CLTI): advanced PAD with ischemic rest pain, ulcers or gangrene. *(Ch. 19)*

chronic obstructive pulmonary disease (COPD): A long-term lung condition in which damaged airways, damaged alveoli or both cause airflow obstruction that does not fully reverse and often worsens over time. *(Ch. 14)*

chronic pain: pain that lasts, or keeps returning, for longer than 3 months *(Ch. 5)*

chronic pancreatitis: A long-lasting fibroinflammatory disease in which ongoing injury scars the pancreas and slowly destroys its digestive and hormone-producing function. *(Ch. 26)*

chronic postsurgical pain: pain that begins or worsens after surgery and persists beyond healing, at least 3 months after surgery *(Ch. 5)*

chronic venous insufficiency (CVI): persistently high pressure in the leg veins from failed valves or blocked veins, causing edema, skin changes and ulcers. *(Ch. 19)*

chronic wound: A wound, also called a wound of long duration, that has stalled in healing because a barrier to healing has not been corrected. *(Ch. 35)*

Chvostek's sign: Twitching of the facial muscles when the facial nerve is tapped; a sign of hypocalcemia, though less specific than Trousseau's sign. *(Ch. 3)*

circle of care: A common term, not defined in PHIPA, for situations in which custodians may assume a patient's implied consent to share personal health information with one another for the patient's health care. *(Ch. 1)*

cirrhosis: Advanced scarring of the liver, with nodules of regenerating cells, that impairs blood flow through the liver and liver function. *(Ch. 26)*

cisgender: Describes a person whose gender identity matches the sex they were assigned at birth. *(Ch. 2)*

CIWA-Ar: the Clinical Institute Withdrawal Assessment for Alcohol, revised; a 10-area scale that measures the current severity of alcohol withdrawal. *(Ch. 11)*

CKD–mineral and bone disorder (CKD–MBD): imbalance of calcium, phosphate, parathyroid hormone and vitamin D in CKD that affects bone and blood vessels *(Ch. 27)*

clinical deterioration: A worsening of a patient's physiological condition that can lead to serious harm or death if it is not recognized and treated. *(Ch. 6)*

Clinical Frailty Scale (CFS): a Canadian, judgment-based nine-level scale that summarizes an older adult's usual fitness or frailty after a clinical encounter. *(Ch. 8)*

clinical judgment: The reasoning a nurse uses to interpret a patient's situation and decide how to respond, observed as the result of critical thinking and decision-making. *(Ch. 1)*

Clinical Judgment Measurement Model (CJMM): NCSBN's layered framework for measuring clinical judgment on the NCLEX; its core is six cognitive skills from recognizing cues to evaluating outcomes. *(Ch. 1)*

Clinical Opiate Withdrawal Scale (COWS): an 11-item clinician-rated scale that rates the severity of opioid withdrawal and tracks it over time. *(Ch. 11)*

clinician-administered MAID: The form of MAID in which a physician or NP gives the substance. *(Ch. 10)*

clipping: Surgery in which the skull is opened and a clip is placed across the neck of an aneurysm. *(Ch. 31)*

closed fracture: A fracture in which the skin over the break is intact. *(Ch. 33)*

closed suction drain: A soft tube from a wound to a compressible bulb that draws out blood and lymph by suction. *(Ch. 29)*

closed-loop communication: An exchange in which the receiver repeats back the message and the sender confirms it, so both know it was understood. *(Ch. 6)*

closed-loop obstruction: an obstruction in which a segment of bowel is blocked at both ends, as in volvulus; it carries a high risk of strangulation. *(Ch. 25)*

closed-system drug-transfer device (CSTD): A device that connects drug containers and tubing so that hazardous drug cannot escape into the air or onto the skin. *(Ch. 9)*

Clostridioides difficile: a spore-forming, toxin-producing anaerobic bacterium that causes diarrhea and colitis, most often after antibiotic use. *(Ch. 4)*

clot retention: blockage of a urinary catheter by blood clots, so the bladder fills and cannot drain. *(Ch. 28)*

clubbing: painless enlargement of the fingertips with loss of the normal angle at the nail bed, linked to lung cancer and chronic lung and heart disease. *(Ch. 12)*

cochlea: The fluid-filled, snail-shaped organ of the inner ear whose hair cells turn sound vibrations into nerve signals. *(Ch. 36)*

cochlear implant: An electronic device, partly placed by surgery, that sends signals straight to the hearing nerve so that people who are severely hard of hearing or profoundly deaf can perceive sound. *(Ch. 36)*

Code of Conduct: CNO's overarching practice standard; it summarizes the behaviour and ethical conduct the public can expect from every Ontario nurse. *(Ch. 1)*

code stroke: A hospital emergency process that brings the stroke team, imaging and laboratory together at once for a person with suspected acute stroke. *(Ch. 31)*

coffee-ground emesis: dark, granular vomit containing blood that has been altered by stomach acid. *(Ch. 24)*

coiling: An endovascular treatment in which a catheter places small coils inside an aneurysm so that blood no longer enters it. *(Ch. 31)*

cold chain: the system that keeps vaccines at the correct temperature, usually +2 °C to +8 °C, from manufacturer to patient. *(Ch. 21)*

colloid: An IV solution containing large molecules, such as albumin, that stay mostly in the blood vessels. *(Ch. 3)*

colonization: The presence of an organism on or in the body without signs of illness; a colonized person can still spread the organism. *(Ch. 4)*

colonoscopy: examination of the whole colon with a flexible scope, which allows polyps to be removed and tissue samples taken. *(Ch. 25)*

colorectal cancer: cancer of the colon or rectum, which can develop from an adenomatous polyp. *(Ch. 25)*

colostomy: an ostomy that brings part of the colon to the abdominal surface. *(Ch. 25)*

commercial tobacco: Manufactured tobacco products, such as cigarettes, chew and snuff, that contain added chemicals and cause addiction and disease. *(Ch. 14)*

comminuted fracture: A fracture in which the bone breaks into three or more pieces. *(Ch. 33)*

communication access: The ability of a person to understand and be understood in the way that works for them, with the supports they need. *(Ch. 36)*

community-acquired pneumonia (CAP): pneumonia that begins outside hospital, including in long-term care. *(Ch. 13)*

compartment syndrome: A rise in pressure within a closed muscle compartment that cuts off blood flow to the muscles and nerves inside it; a surgical emergency. *(Ch. 33)*

compassion fatigue: The emotions and behaviours that can result from repeatedly learning about, and caring for, other people's suffering and trauma. *(Ch. 10)*

compensated cirrhosis: Cirrhosis without overt ascites, variceal bleeding or overt hepatic encephalopathy. *(Ch. 26)*

compensated respiratory acidosis: A high PaCO2 balanced by a rise in bicarbonate retained by the kidneys, so the pH is near normal. *(Ch. 14)*

compensated shock: An early stage of shock in which the body's responses keep blood pressure near normal while signs such as a fast heart rate and cool skin appear. *(Ch. 6)*

compensation: The body's response to a primary acid–base disorder, in which the other system (lungs or kidneys) changes in the opposite direction to move pH back toward normal. *(Ch. 3)*

competence: The knowledge, skill and judgment an individual nurse needs to perform an activity safely; it changes over time and is maintained through continuing learning. *(Ch. 1)*

complete blood count (CBC): a blood test that reports hemoglobin, hematocrit, red cell count and indices, white cell count and differential, and platelet count *(Ch. 20)*

complete injury: A spinal cord injury with no sensation or movement preserved in the lowest sacral segments (S4–S5). *(Ch. 32)*

compliance: how easily the lungs and chest wall stretch; low compliance makes each breath take more effort. *(Ch. 12)*

comprehensive pain assessment: an in-depth assessment of pain's onset, location, quality, intensity, timing, aggravating and relieving factors, effects on function, the person's goals and treatment history *(Ch. 5)*

compression ultrasound: ultrasound in which a vein that will not collapse under probe pressure shows a clot. *(Ch. 19)*

computed tomography (CT): An imaging test that uses a rotating X-ray beam to build cross-sectional images; fast and useful for finding bleeding in the head. *(Ch. 30)*

concern about falling: Worry about falling, the term the World Falls Guidelines prefer to "fear of falling"; it can lead a person to avoid activity and lose strength and balance. *(Ch. 8)*

concussion: A type of mild traumatic brain injury from a force that moves the brain within the skull, causing neurologic changes that usually resolve on their own, with normal standard imaging. *(Ch. 32)*

conductive hearing loss: Hearing loss caused by a problem in the outer or middle ear that stops sound from reaching a normal inner ear. *(Ch. 36)*

Confusion Assessment Method (CAM): a widely used delirium screening approach that judges acute change or fluctuation, inattention, disorganized thinking and level of consciousness. *(Ch. 8)*

Confusion Assessment Method for the ICU: A delirium screening tool for critically ill patients, including those who cannot speak, based on four features. *(Ch. 15)*

congenital syphilis: Syphilis passed from a pregnant person to the fetus. *(Ch. 29)*

conscientious objection: A health professional's refusal, for reasons of conscience or religion, to take part in a lawful service such as MAID; nurses must transfer care without abandoning the patient. *(Ch. 10)*

Consent and Capacity Board: An independent Ontario tribunal that hears disputes about capacity findings, substitute decision-making and withdrawal of life-sustaining treatment. *(Ch. 10)*

conservative kidney management (CKM): planned, active, person-centred care for kidney failure that does not include dialysis, combining kidney care with palliative care principles. *(Ch. 27)*

consolidation: the filling of alveoli with fluid, cells and debris so that part of the lung becomes solid and airless. *(Ch. 13)*

constipation: Stools that are infrequent, hard or difficult to pass, often with straining or a sense of incomplete emptying. *(Ch. 25)*

contact precautions: Precautions for organisms spread by direct or indirect contact; they include a gown, gloves, dedicated equipment and, usually, a single room. *(Ch. 4)*

contingency management: a non-drug treatment that gives small tangible rewards for meeting treatment goals. *(Ch. 11)*

continuous bladder irrigation (CBI): constant flow of sterile 0.9% sodium chloride into and out of the bladder through a three-way catheter to prevent clots. *(Ch. 28)*

continuous glucose monitoring (CGM): measurement of interstitial glucose every few minutes by a sensor under the skin *(Ch. 22)*

continuous positive airway pressure: A form of NIV that delivers one steady pressure throughout the breath to keep airways and alveoli open. *(Ch. 15)*

continuous positive airway pressure (CPAP): A machine that delivers air through a mask at a set pressure to hold the upper airway open during sleep. *(Ch. 14)*

contractility: The strength of the heart muscle's contraction, apart from how much it was stretched by filling. *(Ch. 16)*

contracture: A fixed shortening of muscles and joint tissues that stops a joint from straightening fully. *(Ch. 33)*

contrast-associated acute kidney injury: A decline in kidney function after contrast dye, a concern mainly when eGFR is 30 mL/min/1.73 m² or less or acute kidney injury is already present. *(Ch. 17)*

controlled act: An activity listed in the Regulated Health Professions Act, 1991 that may cause harm and that only authorized people may perform. *(Ch. 1)*

controller: An inhaled medicine used regularly to reduce airway inflammation or keep airways open, preventing symptoms and flare-ups. *(Ch. 14)*

COPD Assessment Test (CAT): A short questionnaire that measures the effect of COPD on daily life; a score of 10 or more shows a moderate to high symptom burden. *(Ch. 14)*

cornea: The clear, curved front surface of the eye, which bends incoming light to help focus it. *(Ch. 36)*

corneal abrasion: A scratch in the outer layer of the cornea that causes pain, tearing and light sensitivity. *(Ch. 36)*

coronary artery bypass grafting (CABG): Surgery that carries blood around blocked coronary arteries using arterial or venous grafts. *(Ch. 17)*

correction insulin: extra rapid- or short-acting insulin added to the scheduled dose when glucose is above target *(Ch. 22)*

corticosteroid: A medicine related to the body's own cortisol that quickly reduces inflammation and immune activity; long-term use suppresses the body's cortisol production. *(Ch. 34)*

corticosteroid-dependent: Unable to stop corticosteroids within three months, relapsing within three months of stopping, or needing two or more courses in a year. *(Ch. 25)*

cortisol: the main glucocorticoid hormone; released under ACTH control, it helps maintain blood pressure and blood glucose and rises during stress. *(Ch. 23)*

costovertebral angle: The angle on the back between the lowest rib and the spine; tenderness here suggests kidney involvement. *(Ch. 28)*

COVID-19: the respiratory illness caused by the SARS-CoV-2 virus. *(Ch. 13)*

COX-2 inhibitor: an NSAID that acts mainly on the COX-2 form of the enzyme, such as celecoxib *(Ch. 5)*

crackles: brief, non-musical, discontinuous popping sounds, usually heard when breathing in; described as fine or coarse. *(Ch. 12)*

craniotomy: Surgery in which part of the skull is opened to reach the brain. *(Ch. 30)*

creatinine: a waste product of muscle activity, filtered by the kidneys; its blood level rises as GFR falls and depends on muscle mass *(Ch. 27)*

critical value: a laboratory result far enough outside the reference range that the laboratory reports it to the care team at once *(Ch. 20)*

Critical-Care Pain Observation Tool (CPOT): an observational tool scoring four behaviours from 0 to 8 for critically ill adults who cannot self-report *(Ch. 5)*

Crohn disease: A form of IBD that can affect any part of the gut from mouth to anus, in patchy segments, with inflammation through the full thickness of the bowel wall. *(Ch. 25)*

crossmatch: a test, serologic or electronic, that confirms donor red cells are compatible with the patient's plasma. *(Ch. 20)*

cryoprecipitate: a small-volume plasma component rich in fibrinogen. *(Ch. 20)*

crystalloid: An IV solution of water with electrolytes, glucose or both. *(Ch. 3)*

CT angiography (CTA): CT imaging with contrast dye that shows the arteries of the neck and brain and where an artery is blocked. *(Ch. 31)*

CT pulmonary angiography (CTPA): A CT scan with IV contrast that shows clots in the pulmonary arteries; the usual imaging test for pulmonary embolism. *(Ch. 15)*

cue: A piece of patient information, such as a sign, symptom, test result or comment, that may signal a problem. *(Ch. 1)*

cuff: A balloon near the tip of some tracheostomy and endotracheal tubes that seals the trachea when inflated. *(Ch. 12)*

Cullen sign: Bruising around the umbilicus caused by blood tracking from behind the peritoneum; rare and not specific to pancreatitis, but a sign of serious disease. *(Ch. 26)*

cultural competence: The ability to reflect on one's own cultural values and to build the knowledge and skills to plan care that respects other people's values and beliefs. *(Ch. 2)*

cultural humility: A lifelong process of self-reflection on one's own biases, privilege and power, in which the provider approaches each person as a learner. *(Ch. 2)*

cultural safety: An outcome, judged by the person receiving care, in which care is respectful, free of racism and discrimination, and attentive to power imbalances in the health system. *(Ch. 2)*

CURB-65: a five-item pneumonia severity score (confusion, urea, respiratory rate, blood pressure, age 65 or older) that helps decide where a patient should be treated. *(Ch. 13)*

Cushing disease: Cushing syndrome caused by an ACTH-secreting pituitary adenoma. *(Ch. 23)*

Cushing syndrome: the signs and symptoms of prolonged, inappropriately high glucocorticoid exposure, most often from prescribed glucocorticoids. *(Ch. 23)*

Cushing triad: A late sign of raised intracranial pressure: high blood pressure, a slow heart rate and an irregular breathing pattern or apnea. *(Ch. 30)*

cystitis: Infection limited to the bladder, usually causing dysuria, urgency, frequency and suprapubic pain. *(Ch. 28)*

cytokine release syndrome: a surge of inflammatory signals after some immune therapies, such as CAR T-cell therapy, causing high fever and low blood pressure. *(Ch. 9)*

cytokines: Small proteins released by immune cells that carry signals between cells and promote or damp down inflammation. *(Ch. 4)*

D-dimer: A fragment released when fibrin breaks down; a normal level makes pulmonary embolism unlikely when pretest probability is not high. *(Ch. 15)*

daily weight: A weight taken at the same time each day on the same scale with similar clothing, used to track short-term changes in body fluid. *(Ch. 3)*

data sovereignty: The right of a People to govern the collection, ownership and use of data about themselves. *(Ch. 2)*

dead space: air that reaches alveoli with little or no blood flow and so takes no part in gas exchange. *(Ch. 12)*

Deaf: A cultural identity, written with a capital D, of people who share Deaf culture and use a signed language as their main language. *(Ch. 36)*

debriefing: The checklist phase completed at the end of an operation, before the patient is moved out of the operating room, covering counts, specimens, equipment problems and the recovery plan. *(Ch. 7)*

decannulation: Removal of a tracheostomy tube from the trachea, planned or accidental. *(Ch. 12)*

decompensated cirrhosis: Cirrhosis in which overt ascites, variceal bleeding or overt hepatic encephalopathy has developed. *(Ch. 26)*

decompression: drainage of a kidney blocked by a stone, by ureteral stent or nephrostomy tube; urgent when the blocked kidney is infected. *(Ch. 28)*

deep tissue pressure injury (DTPI): A pressure injury that starts near the bone and shows as persistent, non-blanching discolouration or a blood blister; on darker skin it may not look purple or maroon. *(Ch. 35)*

deep vein thrombosis (DVT): A blood clot in a deep vein, usually of the leg or pelvis, and the usual source of a pulmonary embolism. *(Ch. 15)*

defibrillation: An unsynchronized shock delivered immediately to treat ventricular fibrillation, pulseless VT or polymorphic VT. *(Ch. 16)*

dehiscence: separation of the edges of a closed surgical incision, with or without exposure of the tissues or organs beneath. *(Ch. 7)*

delabelling: removing an inaccurate allergy label after the history is reviewed and, when needed, testing or a supervised challenge is done. *(Ch. 21)*

delayed cerebral ischemia: New brain ischemia that develops days after an aneurysmal subarachnoid hemorrhage, often linked to narrowing of brain arteries. *(Ch. 31)*

delayed primary intention: Closure of a contaminated wound after it has been left open for several days. *(Ch. 35)*

delegation: Passing the authority for a controlled act from a regulated professional who holds it, and can perform the act competently, to someone who does not hold it; the delegating professional stays accountable. *(Ch. 1)*

delirium: a sudden, fluctuating disturbance of attention and awareness, with changes in thinking or perception, caused by a medical condition, a drug or several factors together. *(Ch. 8)*

delirium tremens: the most severe form of alcohol withdrawal, with delirium, hallucinations, agitation and autonomic overactivity, usually beginning 48 to 72 hours after the last drink; also called alcohol withdrawal delirium. *(Ch. 11)*

dementia: a group of conditions in which memory and other thinking abilities decline gradually and steadily enough to interfere with daily life. *(Ch. 8)*

demyelination: Damage to or loss of the myelin covering of nerve fibres, which slows or blocks nerve signals. *(Ch. 32)*

dependent rubor: dusky red colour of the foot when the leg hangs down, a sign of advanced arterial disease. *(Ch. 19)*

depolarization: Electrical activation of heart muscle cells, which triggers contraction. *(Ch. 16)*

deprescribing: The planned and supervised process of lowering the dose of, or stopping, a drug that may be doing harm or is no longer helping. *(Ch. 8)*

depression: a sustained disturbance of mood, often with loss of interest or pleasure, that changes how a person thinks, feels and functions. *(Ch. 8)*

dermis: The layer of skin beneath the epidermis that contains collagen and elastic fibres, capillaries, nerve endings, hair follicles and glands. *(Ch. 35)*

desmopressin: a synthetic form of vasopressin used to treat arginine vasopressin deficiency; its most serious adverse effect is hyponatremia. *(Ch. 23)*

determinants of health: The conditions and factors, social, economic, physical, biological and structural, that shape the health of individuals and populations. *(Ch. 2)*

device-related pressure injury: A pressure injury caused by a medical device, usually shaped like the device, and staged with the same system as other pressure injuries. *(Ch. 35)*

diabetes distress: the negative emotions and burden of self-management that come from living with diabetes. *(Ch. 22)*

diabetic foot ulcer: a break in the skin of the foot in a person with diabetes, usually from pressure on a foot that has lost sensation. *(Ch. 22)*

diabetic ketoacidosis (DKA): a hyperglycemic emergency in which insulin deficiency leads to ketone production, metabolic acidosis with a high anion gap, and dehydration. *(Ch. 22)*

diabetic retinopathy: Damage to the retina caused by diabetes. *(Ch. 36)*

diagnostic overshadowing: Attributing a new symptom to an existing diagnosis, such as a disability or mental illness, so that the real cause is missed. *(Ch. 2)*

dialysis disequilibrium syndrome: headache, vomiting, confusion and, in severe cases, seizures caused by brain swelling when urea is removed quickly, most often in early treatments. *(Ch. 27)*

dialyzer: the filter in a hemodialysis machine, in which wastes move from the blood across a membrane into dialysate. *(Ch. 27)*

diarrhea: An increase in loose or watery stools above the person's usual pattern. *(Ch. 25)*

diastolic dysfunction: A stiff ventricle that does not relax and fill normally, raising pressure behind it. *(Ch. 18)*

diffuse axonal injury: Widespread stretching and tearing of nerve fibres caused by rapid acceleration and deceleration of the brain. *(Ch. 32)*

diffusing capacity: A test of how well gas crosses from the alveoli into the blood, measured with a small amount of carbon monoxide. *(Ch. 14)*

diffusion: the movement of a gas from an area of higher partial pressure to one of lower partial pressure, as across the alveolar–capillary membrane. *(Ch. 12)*

digital chest drainage: A chest drainage system that provides suction electronically and measures air leak continuously. *(Ch. 15)*

dilated cardiomyopathy: A cardiomyopathy in which the left ventricle enlarges and contracts weakly. *(Ch. 18)*

direct oral anticoagulant (DOAC): an oral drug that directly blocks factor Xa (apixaban, rivaroxaban, edoxaban) or thrombin (dabigatran). *(Ch. 19)*

direct order: An order given for one specific patient, usually in writing and verbally only in limited situations. *(Ch. 1)*

direct-acting antiviral: A drug that blocks a step in hepatitis C virus replication; taken as tablets for 8 to 24 weeks, these drugs cure most people. *(Ch. 26)*

directive: An order written in advance by an authorized provider for an activity that applies to any patient who meets specified conditions. *(Ch. 1)*

directly observed therapy (DOT): A method in which a trained person watches a patient take each dose of medication, used to support completion of TB treatment. *(Ch. 13)*

disability: An impairment of any kind, such as a physical, mental, cognitive, sensory, learning or communication impairment, that, when it meets a barrier, prevents a person from taking part fully and equally in society. *(Ch. 2)*

discectomy: Surgery that removes the part of a herniated disc that presses on a nerve root. *(Ch. 33)*

disclosure: The process of telling a patient or substitute decision-maker that a patient safety incident occurred, what is known and what will happen next. *(Ch. 1)*

disease-modifying antirheumatic drug (DMARD): A medicine that slows or stops the immune process that damages joints, rather than only relieving symptoms. *(Ch. 34)*

disease-modifying therapy (DMT): A long-term medication that changes the course of MS by acting on the immune system, reducing relapses and slowing disability. *(Ch. 32)*

diseases of public health significance: Infections that Ontario law says must be reported to the area's medical officer of health. *(Ch. 4)*

disseminated intravascular coagulation (DIC): uncontrolled activation of clotting throughout the circulation that consumes platelets and clotting factors and can cause both bleeding and clotting. *(Ch. 20)*

distinctions-based approach: An approach that recognizes First Nations, Inuit and Métis as distinct Peoples with their own histories, rights, governments and priorities, instead of treating them as one group. *(Ch. 2)*

distress: Emotional, social, spiritual, practical or physical suffering that makes coping with cancer harder; called the sixth vital sign. *(Ch. 9)*

distress screening: Routine use of a short standard tool to identify people with cancer who need further assessment or support. *(Ch. 9)*

distributive shock: Shock caused by loss of blood vessel tone and widespread vasodilation, as in sepsis, anaphylaxis or spinal cord injury. *(Ch. 6)*

diverticulitis: Inflammation of one or more diverticula, usually causing left lower quadrant pain and fever. *(Ch. 25)*

diverticulosis: The presence of diverticula, small pouches that bulge outward through weak points in the colon wall. *(Ch. 25)*

door-to-needle time: The time from hospital arrival to the start of thrombolysis. *(Ch. 31)*

DRESS: drug reaction with eosinophilia and systemic symptoms; a delayed, severe drug reaction with rash, fever, swollen lymph nodes, facial swelling, eosinophilia and organ involvement, usually 2 to 6 weeks after a drug is started. *(Ch. 21)*

droplet precautions: Precautions for organisms spread by large respiratory droplets over a short distance; they include a mask and eye protection within 2 metres and a single room or spatial separation. *(Ch. 4)*

drug checking: a service that tests a drug sample to show what it contains. *(Ch. 11)*

drug intolerance: an unwanted, non-immune effect of a drug that occurs at a low or below-therapeutic dose. *(Ch. 21)*

drug-resistant TB: TB caused by bacteria resistant to one or more TB drugs; multidrug-resistant TB is resistant to at least isoniazid and rifampin. *(Ch. 13)*

dry powder inhaler (DPI): A device that holds medicine as a powder released by the patient's own fast, forceful breath. *(Ch. 14)*

dry suction: A chest drainage design in which an adjustable control on the unit, rather than a column of water, sets the level of suction. *(Ch. 15)*

dual antiplatelet therapy (DAPT): Treatment with ASA plus a P2Y12 inhibitor to prevent clots after ACS or stent placement. *(Ch. 17)*

Duke-ISCVID criteria: The 2023 Duke-International Society for Cardiovascular Infectious Diseases criteria, which classify infective endocarditis as definite, possible or rejected using major and minor criteria. *(Ch. 18)*

dumping syndrome: cramping, nausea, diarrhea, faintness and fast heart rate after eating, caused by food moving too quickly into the small intestine. *(Ch. 24)*

duty to accommodate: The obligation under human rights law to adjust services to an individual's disability-related needs in ways that respect dignity and support full participation, short of undue hardship. *(Ch. 2)*

dysarthria: A speech disorder caused by weakness or poor control of the muscles used for talking, producing slurred, slow or soft speech with intact language. *(Ch. 30)*

dyskinesia: Involuntary writhing or jerking movements, often a side effect of long-term levodopa treatment. *(Ch. 32)*

dyspepsia: epigastric pain as the main symptom for at least 1 month. *(Ch. 24)*

dysphagia: A swallowing disorder involving the mouth, pharynx, esophagus or the junction of the esophagus and stomach. *(Ch. 24)*

dysphagia screening: A brief check of swallowing safety, done by a trained professional with a valid tool before a patient with stroke takes anything by mouth. *(Ch. 31)*

dyspnea: The subjective experience of breathing discomfort. *(Ch. 10)*

dysrhythmia: Any heart rhythm other than normal sinus rhythm, whether too fast, too slow, irregular or started from an abnormal site. *(Ch. 16)*

dysuria: Pain or burning on urination. *(Ch. 28)*

early supported discharge: Rehabilitation provided at home by a specialized team so that a person with a mild or moderate stroke can leave hospital sooner. *(Ch. 31)*

early warning score: A number calculated from routine vital signs that reflects how sick a patient is and how urgently a response is needed. *(Ch. 6)*

ecchymosis: a bruise; bleeding under the skin that may look darker than the surrounding skin on darker skin tones. *(Ch. 20)*

echocardiography: Ultrasound imaging of the heart's structure and movement, done through the chest wall (transthoracic) or from the esophagus (transesophageal). *(Ch. 16)*

edema: Excess fluid in the interstitial space. *(Ch. 3)*

Edmonton Obesity Staging System: a five-stage tool that rates the metabolic, physical and mental health effects of obesity. *(Ch. 24)*

Edmonton Symptom Assessment System–revised (ESAS-r): A tool in which patients rate nine common symptoms from 0 to 10. *(Ch. 9)*

effluent: the fluid drained out of the abdomen at the end of a peritoneal dialysis dwell. *(Ch. 27)*

ejection fraction (EF): The percentage of blood in the left ventricle pumped out with each beat, usually measured by echocardiography. *(Ch. 18)*

elder abuse: Any act, single or repeated, or failure to act appropriately that harms or distresses an older person within a relationship in which trust is expected; it may be physical, sexual, psychological or emotional, or financial, or take the form of neglect or abandonment. *(Ch. 8)*

electroencephalography (EEG): A test that records the brain's electrical activity through electrodes on the scalp. *(Ch. 30)*

elevation pallor: blanching of the foot when the leg is raised, a sign of arterial disease. *(Ch. 19)*

embolectomy: Surgical removal of a clot from the pulmonary arteries. *(Ch. 15)*

emergence delirium: confusion, restlessness, agitation or unusual quietness and drowsiness that begins during or soon after waking from general anesthesia. *(Ch. 7)*

emphysema: Destruction of alveolar walls that reduces the surface for gas exchange and the lung's elastic recoil. *(Ch. 14)*

empyema: Infected fluid or pus in the pleural space. *(Ch. 13)*

encephalitis: Inflammation of the brain tissue itself, with signs of neurologic dysfunction such as confusion, behaviour change or seizures. *(Ch. 30)*

end-of-life care: The part of palliative care given when death is expected in the near future, focused on comfort, dignity and family support. *(Ch. 10)*

end-tidal carbon dioxide: The level of CO2 at the end of each exhaled breath; a sustained waveform confirms that an endotracheal tube is in the trachea. *(Ch. 15)*

endocrine therapy: Treatment that blocks the production or action of hormones that some cancers use to grow, such as tamoxifen or an aromatase inhibitor for breast cancer. *(Ch. 29)*

endogenous opioids: the body's own opioid substances, which help reduce pain signals *(Ch. 5)*

endometriosis: A chronic inflammatory condition in which tissue similar to the uterine lining grows outside the uterus, causing pain and sometimes infertility. *(Ch. 29)*

endophthalmitis: A sight-threatening infection inside the eye that can follow eye surgery or a penetrating eye injury. *(Ch. 36)*

endoscopic retrograde cholangiopancreatography (ERCP): A procedure in which an endoscope passed through the mouth into the duodenum is used to image and treat the bile and pancreatic ducts, for example by removing stones. *(Ch. 26)*

endotracheal tube: A tube passed through the mouth or nose and the larynx into the trachea, usually for mechanical ventilation. *(Ch. 12)*

endovascular aneurysm repair (EVAR): repair of an aneurysm with a stent graft placed through the femoral arteries. *(Ch. 19)*

endovascular thrombectomy (EVT): Removal of a clot from a large brain artery with a catheter threaded from an artery in the groin or wrist. *(Ch. 31)*

energy conservation: Planning, pacing and resting before exhaustion to manage fatigue in chronic arthritis. *(Ch. 34)*

ENFit: A connector design for enteral feeding equipment that does not fit IV or other non-enteral ports, used to prevent tubing misconnections. *(Ch. 24)*

enhanced recovery after surgery (ERAS): a set of evidence-based practices across the surgical journey that reduce the stress of surgery and speed recovery. *(Ch. 7)*

enteral nutrition: Feeding into the GI tract; in this chapter, liquid formula given through a feeding tube. *(Ch. 24)*

epidermis: The thin outer layer of skin, without its own blood vessels, that forms a waterproof barrier and contains the pigment-making melanocytes. *(Ch. 35)*

epidural analgesia: delivery of a local anesthetic, often with an opioid, through a catheter into the epidural space. *(Ch. 5)*

epidural anesthesia: local anesthetic given into the epidural space, usually through a catheter that can stay in place for pain relief after surgery. *(Ch. 7)*

epidural hematoma: A collection of blood between the skull and the dura. *(Ch. 32)*

epilepsy: A brain disease marked by a lasting tendency to have seizures, diagnosed by the ILAE's practical definition. *(Ch. 30)*

epinephrine autoinjector: a prefilled, spring-loaded device that injects a fixed dose of epinephrine into the thigh muscle for emergency treatment of anaphylaxis. *(Ch. 6)*

equality: Giving every person the same resources or treatment, whatever their needs. *(Ch. 2)*

equity: Giving people what they need so that each person has a fair chance at good outcomes. *(Ch. 2)*

erectile dysfunction: The inability to get or keep an erection firm enough for satisfying sex. *(Ch. 29)*

erythema nodosum: Tender, warm, raised lumps, usually on the shins, that look pink to red on lighter skin and violet, brown or darker than surrounding skin on darker skin. *(Ch. 25)*

erythrocyte sedimentation rate (ESR): A blood test of how quickly red blood cells settle in a tube; it rises with inflammation but is not specific. *(Ch. 34)*

erythropoiesis-stimulating agent: a drug that acts like erythropoietin to raise red blood cell production in anemia of CKD *(Ch. 27)*

escalation: Moving a concern about a patient to a person or team who can act on it, quickly enough to make a difference. *(Ch. 6)*

eschar: Dry, dark, leathery dead tissue in a wound. *(Ch. 35)*

escharotomy: A surgical cut through the eschar of a deep circumferential burn to relieve pressure on a limb, the chest or the neck. *(Ch. 35)*

esophageal varices: Enlarged, thin-walled veins in the lower esophagus caused by portal hypertension, which can bleed heavily. *(Ch. 26)*

essential care partner: A person the patient or substitute decision-maker identifies to give the physical, psychological and emotional support the patient considers important, whose role differs from that of a visitor. *(Ch. 1)*

estimated glomerular filtration rate (eGFR): a GFR calculated by the laboratory from serum creatinine, age and sex; in Canada increasingly with the race-free 2021 CKD-EPI equation *(Ch. 27)*

euglycemic diabetic ketoacidosis: ketoacidosis with glucose only mildly raised or normal, a rare risk with SGLT2 inhibitors *(Ch. 22)*

evisceration: protrusion of abdominal organs through a dehisced surgical wound; a surgical emergency. *(Ch. 7)*

expressive aphasia: Aphasia in which the person understands more than they can say and struggles to find or form words. *(Ch. 31)*

external beam radiation: radiation delivered from a machine outside the body and aimed at the tumour; the patient does not become radioactive. *(Ch. 9)*

external breast form: A breast prosthesis of foam, silicone or another material, worn inside a bra to restore shape after breast tissue is removed. *(Ch. 29)*

external catheter: A device that collects urine from outside the body, such as a sheath over the penis or a suction device against the vulva. *(Ch. 28)*

external fixator: A frame outside the body joined to the bone by pins or wires that pass through the skin, used to hold a fracture still. *(Ch. 33)*

external ventricular drain: A catheter placed through the skull into a ventricle that measures intracranial pressure and drains cerebrospinal fluid into a closed system. *(Ch. 30)*

extracellular fluid (ECF): All body water outside the cells, made up mainly of interstitial fluid and plasma. *(Ch. 3)*

extraintestinal manifestations: Features of IBD outside the gut, such as joint pain, eye inflammation, mouth ulcers and erythema nodosum. *(Ch. 25)*

extravasation: Leakage of a drug or solution that can damage tissue from a vein into the surrounding tissue. *(Ch. 3)*

exudate: Fluid, proteins and cells that leave blood vessels and collect in inflamed tissue. *(Ch. 4)*

Faces Pain Scale–Revised (FPS-R): a self-report scale of six faces scored 0 to 10, developed for children *(Ch. 5)*

failure to capture: A pacemaker problem in which a pacing spike is not followed by a P wave or QRS. *(Ch. 16)*

failure to rescue: Death of a patient after a complication that develops in hospital; used as a measure of how well a hospital recognizes and treats complications. *(Ch. 6)*

fall: An unintentional event that ends with a person resting on the ground, the floor or another lower level, whether or not an injury occurs. *(Ch. 8)*

fasciotomy: Surgery that cuts open the fascia along a muscle compartment to relieve pressure. *(Ch. 33)*

FAST: Heart & Stroke's memory aid for the most common stroke signs: Face: is it drooping? Arms: can you raise both? Speech: is it slurred or jumbled? Time: to call 9-1-1. *(Ch. 31)*

fat embolism syndrome (FES): An illness, usually after a long-bone or pelvic fracture, in which fat droplets in the blood cause breathing problems, neurologic changes and a petechial rash. *(Ch. 33)*

fear of recurrence: Worry that cancer will return, common after treatment and sometimes severe enough to disrupt daily life. *(Ch. 9)*

febrile neutropenia: Fever in a person with a low neutrophil count, usually after chemotherapy; a medical emergency treated with IV antibiotics within 1 hour. *(Ch. 9)*

febrile non-hemolytic transfusion reaction: fever and chills during or up to 4 hours after a transfusion without destruction of red cells. *(Ch. 20)*

fecal calprotectin: A protein released by white blood cells into the stool; a sensitive but non-specific marker of bowel inflammation. *(Ch. 25)*

fecal immunochemical test (FIT): an at-home screening test that detects tiny amounts of human blood in a stool sample. *(Ch. 25)*

fecal impaction: A mass of hard stool in the rectum or colon that the person cannot pass. *(Ch. 25)*

fecal incontinence: The involuntary loss of liquid or solid stool. *(Ch. 25)*

femoral access: Entry to the arterial system through the femoral artery in the groin for catheterization or PCI. *(Ch. 17)*

femoral neck fracture: A break in the narrow neck of the femur just below the femoral head, inside the hip joint capsule (an intracapsular fracture). *(Ch. 33)*

ferritin: the storage form of iron; serum ferritin is the screening test laboratories prefer when iron deficiency is suspected *(Ch. 20)*

fertility preservation: Storing sperm, eggs, embryos or reproductive tissue, or protecting reproductive organs, before or after cancer treatment so that a person may have biological children later. *(Ch. 9)*

FEV1/FVC ratio: The share of the forced vital capacity blown out in the first second; a reduced ratio shows airflow obstruction. *(Ch. 14)*

fever: A rise in body temperature that occurs as part of the inflammatory response; the threshold for action is set by policy, and older adults may have lower readings. *(Ch. 4)*

fibrinolysis: reperfusion with an intravenous drug that dissolves the fibrin in a coronary clot, used when primary PCI would be delayed. *(Ch. 17)*

fine-needle aspiration (FNA): A procedure in which cells are drawn from a thyroid nodule through a thin needle for examination. *(Ch. 23)*

finger thoracostomy: An emergency procedure in which a provider makes a small incision in the chest wall and opens the pleura with a finger to release trapped air. *(Ch. 15)*

First Nations: The many distinct Indigenous Nations across Canada, each with its own language, laws and protocols; a First Nations person may or may not have Indian status. *(Ch. 2)*

first-degree AV block: Delayed AV conduction in which every P wave is conducted but the PR interval is longer than 0.20 seconds. *(Ch. 16)*

fistula: An abnormal tunnel between the bowel and the skin, bladder, vagina or another loop of bowel. *(Ch. 25)*

flail chest: Three or more ribs each broken in two or more places, leaving a loose segment of chest wall that can move inward on inspiration. *(Ch. 15)*

flare: A period when symptoms of a chronic inflammatory disease suddenly return or worsen. *(Ch. 34)*

fluid resuscitation: Planned intravenous fluid given after a major burn to replace fluid that leaks out of the blood vessels, adjusted to urine output. *(Ch. 35)*

fluid volume deficit: A loss of extracellular fluid volume (hypovolemia). *(Ch. 3)*

fluid volume excess: Too much sodium and water in the extracellular fluid (hypervolemia). *(Ch. 3)*

flutter valve: A one-way valve attached to a chest drain that lets air out of the pleural space without a water seal; sometimes called a Heimlich valve. *(Ch. 15)*

focal seizure: A seizure that starts in networks limited to one hemisphere of the brain. *(Ch. 30)*

food insecurity: Not being able to count on enough food, in quantity or quality, because money is short. *(Ch. 2)*

forced expiratory volume in 1 second (FEV1): The volume of air blown out in the first second of a forced breath. *(Ch. 14)*

forced vital capacity (FVC): The total volume of air blown out in one full, forced breath. *(Ch. 14)*

fracture: A break in the continuity of a bone. *(Ch. 33)*

fracture liaison service: A coordinated program that identifies people with a recent fragility fracture and makes sure they are assessed and treated to prevent another fracture. *(Ch. 33)*

fragility fracture: A fracture from low trauma, such as a fall from standing height, that would not normally break a healthy bone. *(Ch. 33)*

frailty: Reduced physiological reserve that leaves a person less able to recover from a stressor such as surgery. *(Ch. 7)*

free T4: The small unbound fraction of thyroxine in the blood that is available to cells. *(Ch. 23)*

frozen plasma: plasma that contains all the clotting factors, frozen after collection and thawed before use. *(Ch. 20)*

full agonist: an opioid that fully activates the mu receptor, with effects that keep increasing as the dose rises. *(Ch. 5)*

full-thickness burn: A burn that destroys the epidermis and the whole dermis and may extend deeper; it looks white, leathery or charred and has little pain at its centre. *(Ch. 35)*

functional asplenia: loss of the spleen's ability to filter bacteria even though the spleen is present, as in sickle cell disease *(Ch. 20)*

functional decline: Loss of the ability to carry out daily activities such as walking, bathing, dressing and toileting. *(Ch. 8)*

functional incontinence: Leakage because a person cannot reach or use the toilet in time, for example because of limited mobility or dementia. *(Ch. 28)*

gabapentinoid: gabapentin or pregabalin, anticonvulsants used for neuropathic pain that raise the risk of opioid overdose and slowed breathing when combined with opioids *(Ch. 5)*

gastric residual volume (GRV): The volume of fluid drawn back from a gastric feeding tube; no longer checked routinely unless ordered or when signs of intolerance appear. *(Ch. 24)*

gastritis: inflammation of the stomach lining. *(Ch. 24)*

gastroesophageal reflux disease (GERD): a condition in which stomach contents flow back into the esophagus and cause troublesome symptoms, complications or both. *(Ch. 24)*

gastrostomy tube: A feeding tube that passes through the abdominal wall into the stomach, used for longer-term feeding. *(Ch. 24)*

gender identity: A person's internal sense of their own gender, such as being a man, a woman, both or neither. *(Ch. 2)*

gender-affirming care: Care that respects and supports a person's gender identity. *(Ch. 29)*

general anesthesia: a drug-induced state of unconsciousness from which the patient cannot be roused, even by pain. *(Ch. 7)*

generalized seizure: A seizure that starts in networks spread across both hemispheres of the brain. *(Ch. 30)*

genital herpes: A lifelong infection with herpes simplex virus that causes recurrent genital sores and can spread without symptoms. *(Ch. 29)*

genitourinary syndrome of menopause: A group of vulvar, vaginal and lower urinary tract symptoms, such as dryness, painful intercourse and urgency, caused by falling estrogen. *(Ch. 29)*

giant cell arteritis: A vasculitis of large arteries, including those of the head, in adults older than 50 that can cause permanent vision loss if not treated at once. *(Ch. 34)*

Glasgow Coma Scale (GCS): A standard scale that rates eye opening, verbal response and motor response to describe level of consciousness; the components are reported separately, and the total ranges from 3 to 15. *(Ch. 30)*

Glasgow-Blatchford score: a pre-endoscopy risk score for upper GI bleeding that predicts the need for treatment; a score of 1 or less marks very low risk. *(Ch. 24)*

glaucoma: A group of eye diseases in which the optic nerve is progressively and irreversibly damaged and the visual field shrinks. *(Ch. 36)*

Global Leadership Initiative on Malnutrition (GLIM) criteria: International criteria that diagnose malnutrition when a person at risk meets at least one phenotypic criterion (weight loss, low BMI or reduced muscle mass) and at least one etiologic criterion (reduced intake or absorption, or inflammation). *(Ch. 24)*

glomerular filtration rate (GFR): the volume of plasma filtered by the glomeruli each minute; the main measure of kidney function, reported in mL/min/1.73 m^2 *(Ch. 27)*

GLP-1 receptor agonist: a drug that copies the incretin GLP-1, boosting glucose-dependent insulin release, lowering glucagon and slowing stomach emptying *(Ch. 22)*

glucagon: the alpha-cell hormone that raises glucose between meals by making the liver release and produce glucose *(Ch. 22)*

glucocorticoid-induced adrenal insufficiency: adrenal insufficiency caused by long-term glucocorticoid medication suppressing the hypothalamic–pituitary–adrenal axis; it appears when the drug is stopped, reduced or not absorbed, or when stress raises cortisol needs. *(Ch. 23)*

glucose management indicator (GMI): an estimate of A1C calculated from the mean glucose on a CGM report *(Ch. 22)*

goals of care: A discussion during a serious illness about the illness, its likely course and what matters most to the person, used to match treatment options to the person's goals. *(Ch. 10)*

goitre: An enlarged thyroid gland, seen or felt as fullness at the front of the neck. *(Ch. 23)*

gonorrhea: A sexually transmitted infection caused by Neisseria gonorrhoeae, a bacterium that can quickly develop antibiotic resistance. *(Ch. 29)*

Good Samaritan Drug Overdose Act: a 2017 federal law that, when someone calls for emergency help with an overdose, protects the caller and others at the scene from charges of simple possession and related breaches of conditions. *(Ch. 11)*

gout: A form of inflammatory arthritis caused by deposits of monosodium urate crystals in and around joints and in other tissues. *(Ch. 34)*

gout flare: A sudden attack of pain, swelling and warmth in a joint caused by the immune response to urate crystals. *(Ch. 34)*

grade: a description of how abnormal cancer cells look under a microscope, reflecting how well differentiated they are. *(Ch. 9)*

graft-versus-host disease: a complication of allogeneic transplant in which the donor's immune cells react against the recipient's tissues. *(Ch. 20)*

granulation tissue: Moist, bumpy new connective tissue with many capillaries that fills a wound from its base during healing. *(Ch. 35)*

Graves disease: An autoimmune disorder in which antibodies stimulate the TSH receptor and cause hyperthyroidism. *(Ch. 23)*

Grey Turner sign: Bruising of the flanks caused by blood tracking from behind the peritoneum; rare and not specific to pancreatitis, but a sign of serious disease. *(Ch. 26)*

grief: The emotional, physical and spiritual response to loss. *(Ch. 10)*

grievous and irremediable medical condition: An illness, disease or disability that is serious and incurable, with an advanced, irreversible decline in capability and enduring, intolerable suffering that cannot be relieved under conditions the person considers acceptable. *(Ch. 10)*

group and screen: laboratory ABO and RhD typing with a screen for antibodies against red cells; also called type and screen. *(Ch. 20)*

Guillain–Barré syndrome (GBS): An acute immune attack on the peripheral nerves, often after an infection, causing rapidly rising weakness and loss of reflexes. *(Ch. 32)*

Hamilton Early Warning Score (HEWS): A Canadian early warning score developed at hospitals affiliated with Hamilton Health Sciences that adds a delirium screen and graded oxygen scoring to vital signs and level of consciousness. *(Ch. 6)*

hand hygiene: Removing or killing microorganisms on the hands with alcohol-based hand rub or soap and running water. *(Ch. 4)*

harm reduction: practical measures that reduce the harms of substance use without requiring the person to stop using. *(Ch. 5)*

harmful incident: A patient safety incident that reached the patient and caused harm. *(Ch. 1)*

Hashimoto thyroiditis: Chronic autoimmune thyroiditis, the most common cause of hypothyroidism where diets contain enough iodine. *(Ch. 23)*

hazardous drug: A drug that can harm people who handle it because it may damage genes, cause cancer or birth defects, harm fertility, damage organs at low doses, or resembles drugs with these effects. *(Ch. 9)*

healing by primary intention: Healing of a wound whose edges are brought together with sutures, staples or tape, without the need for granulation tissue. *(Ch. 4)*

healing by secondary intention: Healing of an open wound that fills with granulation tissue from the base up. *(Ch. 4)*

healing by tertiary intention: Healing of a wound that is left open for several days and then closed (delayed primary closure), often used for contaminated wounds. *(Ch. 4)*

healing ridge: A firm area of new collagen under a healing incision that is a normal sign of the proliferation phase. *(Ch. 4)*

health care-associated infection (HAI): An infection a person acquires while receiving health care. *(Ch. 4)*

health equity: A state in which every person has a fair opportunity to reach their best possible health, regardless of the social and structural conditions of their lives. *(Ch. 2)*

health inequality: A measurable difference in health between groups of people. *(Ch. 2)*

health inequity: A systematic difference in health between groups that is avoidable and unjust because it results from how resources, power and opportunities are distributed. *(Ch. 2)*

health information custodian: Under PHIPA, a person or organization, such as a hospital, that has custody or control of personal health information while providing health care. *(Ch. 1)*

health literacy: A person's ability to find, understand, judge and share health information in ways that support and improve their health. *(Ch. 1)*

hearing aid: A small electronic device worn in or behind the ear that makes sound louder. *(Ch. 36)*

heart failure (HF): A clinical syndrome in which a structural or functional problem of the heart causes symptoms and signs, supported by raised natriuretic peptides or evidence of congestion. *(Ch. 18)*

heart failure with improved ejection fraction (HFimpEF): Heart failure in which a previously reduced ejection fraction has risen above 40% by at least 10 percentage points. *(Ch. 18)*

heart failure with mildly reduced ejection fraction (HFmrEF): An international term for heart failure with an ejection fraction of 41% to 49%. *(Ch. 18)*

heart failure with nonreduced ejection fraction (HFnrEF): The Canadian term for heart failure with an ejection fraction above 40%, combining HFmrEF and HFpEF. *(Ch. 18)*

heart failure with preserved ejection fraction (HFpEF): An international term for heart failure with an ejection fraction of 50% or more. *(Ch. 18)*

heart failure with reduced ejection fraction (HFrEF): Heart failure with an ejection fraction of 40% or less. *(Ch. 18)*

Heart Team: A multidisciplinary group, including cardiologists, cardiac surgeons, imaging specialists and nurses, that plans valve treatment with the patient. *(Ch. 18)*

Helicobacter pylori (H. pylori): a bacterium that lives in the stomach and causes gastritis, peptic ulcers and some stomach cancers. *(Ch. 24)*

hematemesis: vomiting of bright red blood or clots. *(Ch. 24)*

hematochezia: red or maroon blood passed from the rectum. *(Ch. 24)*

hematocrit: the fraction of blood volume made up of red blood cells; reported in L/L *(Ch. 20)*

hematoma: a collection of blood in the tissues, such as under a surgical incision. *(Ch. 7)*

hematopoiesis: the production of blood cells, which in adults takes place in the bone marrow *(Ch. 20)*

hematuria: blood in the urine, which may make it pink, red or brown or be seen only on testing. *(Ch. 28)*

hemiarthroplasty: Surgery that replaces the femoral head and neck with a prosthesis while leaving the hip socket in place. *(Ch. 33)*

hemiparesis: Weakness of the face, arm or leg on one side of the body. *(Ch. 31)*

hemiplegic shoulder: The shoulder on the weak side after a stroke, which can partly dislocate and become painful. *(Ch. 31)*

hemodialysis: dialysis in which blood passes through a filter (dialyzer) outside the body to remove wastes and extra fluid, then returns to the body. *(Ch. 27)*

hemoglobin: the iron-containing protein in red blood cells that carries oxygen; reported in g/L *(Ch. 20)*

hemolysis: destruction of red blood cells before the end of their normal lifespan *(Ch. 20)*

hemophilia: an inherited lack of clotting factor VIII (hemophilia A) or factor IX (hemophilia B), usually affecting males. *(Ch. 20)*

hemoptysis: coughing up blood. *(Ch. 12)*

hemorrhagic shock: hypovolemic shock caused by bleeding. *(Ch. 6)*

hemorrhagic stroke: A stroke caused by a blood vessel that ruptures and bleeds into or around the brain. *(Ch. 31)*

hemosiderin staining: grey-brown or dark discoloration of the lower leg from iron pigment left by broken-down red blood cells. *(Ch. 19)*

hemothorax: Blood in the pleural space. *(Ch. 15)*

hemovigilance: the surveillance of transfusions and their outcomes to improve safety. *(Ch. 20)*

heparin-induced thrombocytopenia (HIT): an immune reaction to heparin that lowers the platelet count and greatly increases the risk of clotting. *(Ch. 19)*

hepatic encephalopathy (HE): Brain dysfunction caused by liver failure, blood bypassing the liver, or both, ranging from subtle changes to coma. *(Ch. 26)*

hepatitis: Inflammation of the liver. *(Ch. 26)*

hepatitis A: A liver infection spread by the fecal-oral route that does not become chronic and is prevented by vaccine and hand hygiene. *(Ch. 26)*

hepatitis B: A liver infection spread through blood and body fluids that becomes chronic in a minority of infected adults and most infected infants; preventable by vaccine. *(Ch. 26)*

hepatitis C: A liver infection spread mainly through blood that often becomes chronic and is curable with direct-acting antivirals; no vaccine exists. *(Ch. 26)*

hepatocellular carcinoma: Cancer arising from liver cells, a long-term risk of cirrhosis and chronic hepatitis B. *(Ch. 26)*

hepatorenal syndrome: Acute kidney injury in a person with cirrhosis, caused by constriction of the kidneys' blood vessels rather than kidney damage, shock or nephrotoxic drugs. *(Ch. 26)*

HER2: Human epidermal growth factor receptor 2, a cell-surface protein that some breast cancers make in excess; these cancers may respond to HER2-targeted drugs. *(Ch. 29)*

herniation: The displacement of brain tissue, under pressure, from one compartment of the skull into another or through the opening at the base of the skull. *(Ch. 30)*

herpes zoster: Reactivation of the varicella-zoster virus, causing pain and a band of blisters on one side of the body; also called shingles. *(Ch. 35)*

high-alert medication: A drug, such as insulin, an opioid or an anticoagulant, whose errors are especially likely to cause serious harm. *(Ch. 1)*

high-flow device: An oxygen device that delivers a fixed FiO2 whatever the patient's breathing pattern, such as a Venturi mask or high-flow nasal cannula. *(Ch. 12)*

high-flow nasal cannula (HFNC): A system that delivers heated, humidified, blended air and oxygen through wide-bore nasal prongs at high flows and a set FiO2. *(Ch. 12)*

high-output ileostomy: ileostomy output large enough to cause water and sodium depletion, generally more than about 1.5 to 2 L in 24 hours. *(Ch. 25)*

high-sensitivity troponin: A blood test that measures very low levels of cardiac troponin, a protein released from injured heart muscle; reported in ng/L. *(Ch. 16)*

hip dislocation: Displacement of the ball of a hip prosthesis (or a natural femoral head) out of the socket. *(Ch. 33)*

hip fracture: A break in the upper part of the femur near the hip joint. *(Ch. 33)*

HIV non-disclosure: not telling a sexual partner about one's HIV status; a criminal matter in Canada only when there is a realistic possibility of transmission. *(Ch. 21)*

home blood pressure monitoring (HBPM): Readings taken by the person at home with a validated device, using a set schedule such as two readings morning and evening for 1 week. *(Ch. 19)*

homelessness: The situation of a person, family or community that lacks stable, permanent and suitable housing and has no immediate prospect, means or ability to obtain it. *(Ch. 2)*

hormone: A chemical messenger released into the blood by a gland that acts on target cells elsewhere in the body. *(Ch. 23)*

hormone receptor status: Whether cancer cells carry estrogen receptors, progesterone receptors or both, which predicts whether hormone-blocking treatment will work. *(Ch. 29)*

hormone therapy: cancer treatment that blocks the production or action of hormones that some cancers need to grow. *(Ch. 9)*

hospice: In Canada, a term used interchangeably with palliative care and often applied to community-based care; a hospice residence is one setting for care near the end of life. *(Ch. 10)*

hospital-acquired pneumonia (HAP): pneumonia that was not incubating at admission and appears 48 hours or more after admission. *(Ch. 13)*

hospital-associated disability: a new loss of ability to perform a basic activity of daily living that develops during a hospital stay and is not caused directly by the illness itself. *(Ch. 8)*

huff cough: A forced breath out through an open mouth and throat (the forced expiratory technique), used to move secretions. *(Ch. 12)*

human immunodeficiency virus (HIV): a retrovirus that infects CD4 T helper cells and, without treatment, gradually destroys the immune system. *(Ch. 21)*

human papillomavirus: A common sexually transmitted virus; persistent infection with high-risk types causes cervical cancer. *(Ch. 29)*

humidification: Adding water vapour to inspired gas to prevent drying of the airway. *(Ch. 12)*

hydrocephalus: A buildup of cerebrospinal fluid in the ventricles of the brain, often because its flow is blocked. *(Ch. 30)*

hydroxyurea: an oral drug that raises fetal hemoglobin and reduces sickling; handled as a hazardous drug *(Ch. 20)*

hyperactive delirium: delirium in which the person is restless, agitated or fearful and may have hallucinations. *(Ch. 8)*

hyperalgesia: more pain than expected from a stimulus that normally causes pain *(Ch. 5)*

hypercalcemia: A serum calcium above the reference range. *(Ch. 3)*

hypercalcemia of malignancy: A high blood calcium level caused by cancer, often through parathyroid hormone–related peptide or bone metastases. *(Ch. 9)*

hypercapnia: A raised level of carbon dioxide in arterial blood (PaCO2 above 45 mm Hg). *(Ch. 12)*

hypercapnic respiratory failure: Type 2 respiratory failure; ventilation fails, so the PaCO2 rises above the normal range, often with a low pH. *(Ch. 15)*

hyperglycemic hyperosmolar state (HHS): a hyperglycemic emergency with very high glucose, high plasma osmolality and severe dehydration, but minimal or no acidosis. *(Ch. 22)*

hyperinflation: An abnormally large lung volume caused by air trapping, which flattens the diaphragm and makes breathing less efficient. *(Ch. 14)*

hyperkalemia: A serum potassium above the reference range; it can cause peaked T waves and fatal dysrhythmias. *(Ch. 3)*

hypernatremia: A serum sodium above the reference range, usually from too little water relative to sodium. *(Ch. 3)*

hyperoxia: More oxygen in the blood than the body needs; in acutely ill adults, liberal oxygen use is linked to higher mortality. *(Ch. 12)*

hyperpigmentation: darkening of the skin and mucous membranes caused by high ACTH in primary adrenal insufficiency, most visible in creases, gums, scars and sun-exposed skin. *(Ch. 23)*

hypersensitivity: an excessive or misdirected immune response that damages the body's own tissues; grouped into types I to IV. *(Ch. 21)*

hypertension: Blood pressure persistently at or above 130/80 mm Hg, taken with a validated device and standardized technique (Goupil et al., 2025). *(Ch. 19)*

hypertensive emergency: Severe hypertension with new or worsening damage to the brain, eyes, heart, kidneys or large arteries. *(Ch. 19)*

hypertensive urgency: Severe hypertension without acute target-organ damage; treated with oral drugs and gradual lowering. *(Ch. 19)*

hyperthyroidism: Thyrotoxicosis caused by a thyroid gland that makes too much hormone. *(Ch. 23)*

hypertonic: Having a higher tonicity than plasma, so water moves out of cells. *(Ch. 3)*

hypertrophic cardiomyopathy: An often inherited cardiomyopathy in which the ventricular wall thickens abnormally and may block outflow from the left ventricle. *(Ch. 18)*

hyphema: Bleeding inside the front of the eye, usually after blunt injury; a possible sign of serious injury to the eyeball. *(Ch. 36)*

hypoactive delirium: delirium in which the person is quiet, drowsy, slow and withdrawn; it is often missed. *(Ch. 8)*

hypocalcemia: A serum calcium below the reference range, causing nerve and muscle overexcitability. *(Ch. 3)*

hypodermis: The fatty subcutaneous layer beneath the dermis that insulates, cushions and stores energy; it has a poor blood supply. *(Ch. 35)*

hypoglycemia: a blood glucose level low enough to cause symptoms or risk harm; Diabetes Canada's 2023 update uses an alert value below 3.9 mmol/L and grades severity in three levels. *(Ch. 22)*

hypokalemia: A serum potassium below the reference range; it can cause weakness, ileus and dysrhythmias. *(Ch. 3)*

hypomagnesemia: A serum magnesium below the reference range, often with low potassium and low calcium. *(Ch. 3)*

hyponatremia: A serum sodium below the reference range, usually from too much water relative to sodium. *(Ch. 3)*

hypoparathyroidism: Too little PTH, causing low calcium; most often caused by neck surgery. *(Ch. 23)*

hypothesis: A possible explanation for a group of cues that the nurse tests against further information. *(Ch. 1)*

hypothyroidism: A deficiency of thyroid hormone that slows metabolism throughout the body. *(Ch. 23)*

hypotonic: Having a lower tonicity than plasma, so water moves into cells. *(Ch. 3)*

hypovolemic shock: Shock caused by too little blood or fluid volume in the vessels. *(Ch. 6)*

hypoxemia: a low level of oxygen in the arterial blood. *(Ch. 12)*

hypoxemic respiratory failure: Type 1 respiratory failure; oxygenation fails, with a PaO2 below about 60 mm Hg and a normal or low PaCO2. *(Ch. 15)*

hypoxia: too little oxygen in the body's tissues. *(Ch. 12)*

hypoxic pulmonary vasoconstriction: narrowing of small pulmonary arteries in poorly ventilated lung, which steers blood toward better-ventilated alveoli. *(Ch. 12)*

hysterectomy: Surgical removal of the uterus; a total hysterectomy also removes the cervix. *(Ch. 29)*

ICS–formoterol reliever: Budesonide–formoterol used as needed for symptoms, so each reliever dose also treats inflammation. *(Ch. 14)*

idiopathic pulmonary fibrosis (IPF): A scarring interstitial lung disease of unknown cause. *(Ch. 14)*

IgE: the antibody class that binds mast cells and basophils and drives type I allergic reactions. *(Ch. 21)*

ileal conduit: a channel made from a short piece of small intestine that carries urine from the ureters to a stoma on the abdomen. *(Ch. 28)*

ileostomy: an ostomy that brings the end of the ileum to the abdominal surface; its output is liquid to paste-like. *(Ch. 25)*

illness trajectory: The path a health condition takes over time, from prevention through acute illness, recovery, chronic management and end of life, and the care needed at each point. *(Ch. 1)*

immune checkpoint inhibitor: a drug that blocks signals cancer cells use to switch off T cells, allowing the immune system to attack the cancer. *(Ch. 9)*

immune reconstitution inflammatory syndrome (IRIS): an inflammatory worsening of an infection's signs, usually in the first weeks to months after ART starts, caused by the recovering immune system reacting to organisms already present. *(Ch. 21)*

immune thrombocytopenia (ITP): an acquired autoimmune disorder with a low platelet count, causing bruising, petechiae and sometimes mucosal bleeding. *(Ch. 20)*

immune-related adverse event: an inflammatory reaction in a healthy organ caused by immune checkpoint inhibitor therapy, such as colitis, pneumonitis, hepatitis, endocrine disorders or rash. *(Ch. 9)*

immunocompromised: having immune defences weakened by a disease or its treatment. *(Ch. 21)*

immunodeficiency: a state in which the immune system cannot defend the body adequately; primary when built into the immune system, secondary when acquired. *(Ch. 21)*

immunosenescence: the natural, gradual decline in immune function that comes with age. *(Ch. 21)*

immunotherapy: Cancer treatment, such as immune checkpoint inhibitors, that helps the immune system attack cancer cells. *(Ch. 13)*

impaired awareness of hypoglycemia: weak or absent warning symptoms of a low glucose, so that confusion or loss of consciousness may be the first sign. *(Ch. 22)*

implantable cardioverter-defibrillator (ICD): An implanted device that detects VT or VF and treats it with rapid pacing or a shock. *(Ch. 16)*

implicit bias: An attitude or stereotype that operates outside a person's awareness and shapes judgments and actions without the person intending it. *(Ch. 2)*

inactivated vaccine: a vaccine containing an organism or its parts that cannot replicate; non-live vaccines also include toxoid, subunit and recombinant vaccines. *(Ch. 21)*

inadvertent perioperative hypothermia: an unplanned core body temperature below 36.0 °C around the time of surgery. *(Ch. 7)*

incentive spirometer: A hand-held device that shows how deeply a patient breathes in, encouraging slow, full breaths. *(Ch. 7)*

incomplete injury: A spinal cord injury with some sensation or voluntary movement preserved in the lowest sacral segments. *(Ch. 32)*

incontinence-associated dermatitis (IAD): A form of MASD caused by urine, stool or both, usually affecting the perineum, buttocks and upper inner thighs. *(Ch. 35)*

incretins: gut hormones, mainly GLP-1 and GIP, released after meals that boost insulin release when glucose is high *(Ch. 22)*

independent double check: A safety check in which a second practitioner separately verifies a medication, dose, route, calculation and pump settings against the order without seeing the first practitioner's result, before the results are compared. *(Ch. 1)*

Indian Act: The federal law, first passed in 1876, that defines who is registered as an "Indian" and has governed many aspects of First Nations life, including reserves and band governance. *(Ch. 2)*

Indian hospitals: Racially segregated federal hospitals for Indigenous patients, operated from 1936 to 1981 and first set up to isolate people with tuberculosis; patients experienced abuse in them. *(Ch. 2)*

Indian status: The legal standing of a First Nations person registered under the Indian Act; a legal category, not an identity. *(Ch. 2)*

Indigenous patient navigator: A hospital or health-system staff member who supports Indigenous patients and families, improves communication with the care team and connects patients with cultural, spiritual and community services. *(Ch. 2)*

Indigenous-specific racism: The particular stereotyping, bias and prejudice directed at Indigenous Peoples, rooted in settler colonialism, that sustains power imbalances and unequal outcomes. *(Ch. 2)*

induration: Hardening of tissue that can be felt on palpation, often a sign of inflammation or deep damage. *(Ch. 35)*

indwelling urinary catheter: A tube passed into the bladder through the urethra or abdominal wall, held by a balloon and draining continuously into a closed bag. *(Ch. 28)*

infection: Entry of microorganisms into body tissues, where they multiply. *(Ch. 4)*

infective endocarditis (IE): Infection of the inner lining of the heart, usually a valve or implanted material. *(Ch. 18)*

infiltration: Leakage of IV fluid from the vein into the surrounding tissue. *(Ch. 3)*

inflammation: The body's protective response to tissue injury or infection, which brings fluid, proteins and white cells to the area, removes the cause and prepares for repair. *(Ch. 4)*

inflammatory bowel disease (IBD): A group of chronic, relapsing conditions in which the immune system keeps the lining of the gut inflamed; the main forms are Crohn disease and ulcerative colitis. *(Ch. 25)*

inflammatory myopericardial syndrome: The 2025 ESC umbrella term for pericarditis and myocarditis, which share causes and often overlap. *(Ch. 18)*

influenza: an acute respiratory illness caused by influenza viruses, classically with sudden fever, cough and muscle aches. *(Ch. 13)*

informed consent: Agreement to a treatment that relates to that treatment, is given voluntarily, is not obtained by misrepresentation or fraud, and is based on information about the treatment's nature, benefits, risks, side effects, alternatives and the consequences of refusing it. *(Ch. 1)*

inhalation injury: Damage to the airway and lungs from heat, smoke or toxic gases, suspected after a fire in an enclosed space. *(Ch. 35)*

inhaled corticosteroid (ICS): An inhaled anti-inflammatory controller, such as fluticasone or budesonide. *(Ch. 14)*

initiation: The authority, set out in regulation, for RNs and RPNs to decide on their own to perform certain controlled acts without an order; not available in Ontario public hospitals. *(Ch. 1)*

innate immunity: the inborn, rapid first line of defence, including barriers, phagocytes and complement, which responds the same way each time and has no memory. *(Ch. 21)*

inner cannula: A removable tube inside a tracheostomy tube that can be cleaned or replaced, or removed at once if secretions block it. *(Ch. 12)*

inner ear: The innermost part of the ear, containing the cochlea for hearing and the vestibular organs for balance. *(Ch. 36)*

inpatient surgery: Surgery after which the patient is admitted to hospital. *(Ch. 7)*

insulin: the beta-cell hormone that moves glucose into cells, stops the liver releasing glucose and holds back fat breakdown and ketone formation *(Ch. 22)*

insulin resistance: a reduced response of body cells to insulin, so more insulin is needed to keep glucose normal *(Ch. 22)*

insulin secretagogue: a drug, such as a sulfonylurea or meglitinide, that makes the pancreas release insulin whatever the glucose level *(Ch. 22)*

insured health services: Under the Canada Health Act, medically necessary hospital services, medically required physician services and surgical-dental services that require a hospital. *(Ch. 1)*

Integrated Nutrition Pathway for Acute Care (INPAC): A Canadian pathway for hospital nutrition care that moves from screening with the CNST to assessment, standard, advanced and specialized nutrition care, and discharge planning. *(Ch. 24)*

interdialytic weight gain: weight gained from fluid between hemodialysis sessions. *(Ch. 27)*

interferon-gamma release assay (IGRA): A blood test that detects TB infection by measuring interferon-gamma released by T cells exposed to M. tuberculosis proteins; not affected by BCG vaccine. *(Ch. 13)*

intergenerational effects: Harms of colonial policies that pass from one generation to the next, for example through disrupted families, lost languages and unresolved trauma. *(Ch. 2)*

Interim Federal Health Program (IFHP): A federal program, run by Immigration, Refugees and Citizenship Canada, that provides limited, temporary health coverage to eligible refugees, refugee claimants and certain others until they qualify for provincial or territorial insurance. *(Ch. 2)*

intermittent catheterization: Passing a catheter into the bladder to drain it and then removing it; done with sterile technique in hospital and clean technique at home. *(Ch. 28)*

intermittent claudication: cramping or aching leg pain that comes on with walking at a predictable distance and eases with rest. *(Ch. 19)*

intermittent pneumatic compression (IPC): leg sleeves that inflate in cycles to squeeze the legs and move blood toward the heart, used to prevent venous thromboembolism. *(Ch. 7)*

internal fixation: Plates, screws, rods or nails placed in surgery to hold a broken bone from inside. *(Ch. 33)*

International Dysphagia Diet Standardisation Initiative (IDDSI): The international framework that describes drink thickness and food texture on a continuum of eight levels numbered 0 to 7. *(Ch. 24)*

international normalized ratio (INR): A standardized blood test of clotting time used to adjust warfarin. *(Ch. 18)*

International Prostate Symptom Score (IPSS): a short questionnaire used to rate the severity of lower urinary tract symptoms and follow the response to treatment. *(Ch. 28)*

intersectionality: A way of understanding how a person's social positions, such as race, gender, disability, age, income and immigration status, combine to shape experiences of advantage and disadvantage. *(Ch. 2)*

interstitial fluid: Fluid in the spaces between cells in the tissues. *(Ch. 3)*

interstitial lung disease (ILD): A group of disorders that inflame or scar the lung tissue between the alveoli and blood vessels, causing a restrictive pattern. *(Ch. 14)*

intertrochanteric fracture: A break in the femur between the greater and lesser trochanters, outside the hip joint capsule. *(Ch. 33)*

intolerance (drug): an expected, non-immune side effect of a drug, such as nausea, diarrhea or headache. *(Ch. 4)*

intracellular fluid (ICF): Body water inside the cells, about two-thirds of the total. *(Ch. 3)*

intracerebral hemorrhage (ICH): Bleeding into the brain tissue itself that is not caused by trauma. *(Ch. 31)*

intracranial pressure: The pressure inside the skull, produced by the brain tissue, blood and cerebrospinal fluid it contains. *(Ch. 30)*

intradialytic hypotension: a fall in blood pressure during hemodialysis, linked with rapid fluid removal and with poorer outcomes. *(Ch. 27)*

intraocular pressure (IOP): The pressure inside the eye, set by the balance between aqueous humour production and drainage. *(Ch. 36)*

intraoperative: The phase from arrival in the operating room until transfer to the recovery area. *(Ch. 7)*

intraoperative floppy iris syndrome: a problem with the iris during cataract or glaucoma surgery linked to alpha-blockers such as tamsulosin. *(Ch. 28)*

intravascular fluid: The fluid within blood vessels; the plasma. *(Ch. 3)*

intravesical BCG: live, weakened bacillus Calmette-Guérin bacteria instilled into the bladder to treat non-muscle-invasive bladder cancer. *(Ch. 28)*

intubation: Placement of an endotracheal tube through the mouth into the trachea. *(Ch. 15)*

Inuit: The Indigenous People of Inuit Nunangat, many of whom now also live in southern cities; one person is an Inuk. *(Ch. 2)*

Inuit Child First Initiative: A federal initiative that helps Inuit children get the health, social and educational services and supports they need. *(Ch. 2)*

Inuit Nunangat: The Inuit homeland of land, water and ice, made up of the Inuvialuit Settlement Region, Nunavut, Nunavik and Nunatsiavut. *(Ch. 2)*

ionized calcium: The free, physiologically active fraction of plasma calcium, about half of the total. *(Ch. 3)*

iron chelation: drug treatment that binds excess iron so that it can be excreted *(Ch. 20)*

iron deficiency anemia: anemia caused by too little iron for hemoglobin production, with small, pale red cells and low ferritin *(Ch. 20)*

iron overload: excess body iron, usually from repeated transfusion, that damages the heart, liver and endocrine glands *(Ch. 20)*

irritant: A drug that causes pain or inflammation at the IV site or along the vein, usually without lasting tissue damage. *(Ch. 9)*

ischemic core: The central area of an ischemic stroke, where blood flow is lowest and damage quickly becomes permanent. *(Ch. 31)*

ischemic stroke: A stroke in which a blocked artery deprives part of the brain, spinal cord or retina of blood until cells die. *(Ch. 31)*

isotonic: Having about the same tonicity as plasma, so cells keep their size. *(Ch. 3)*

JAK inhibitor: An oral targeted synthetic DMARD that blocks Janus kinase enzymes inside immune cells, interrupting signals from many inflammatory messengers. *(Ch. 34)*

jaundice: yellow colour of the sclera, mucous membranes and skin caused by raised bilirubin *(Ch. 20)*

jejunostomy tube: A feeding tube that passes through the abdominal wall into the jejunum, usually used with a continuous feed by pump. *(Ch. 24)*

joint protection: Ways of doing daily tasks that reduce strain on painful joints, such as using larger joints, avoiding tight gripping and using aids. *(Ch. 34)*

Jordan's Principle: A principle that aims to ensure First Nations children can get essential government services without gaps or delays caused by their identity or where they live. *(Ch. 2)*

Joyce's Principle: A principle set out in 2020 by the Council of the Atikamekw of Manawan and the Atikamekw Nation Council, after the death of Joyce Echaquan, that aims to guarantee Indigenous people equitable access to health and social services without discrimination, and respect for Indigenous knowledge in health. *(Ch. 2)*

jugular venous distension: Visible filling of the neck veins with the head raised 30 to 45 degrees, a sign of high venous pressure. *(Ch. 3)*

jugular venous pressure (JVP): The vertical height of the internal jugular venous pulsation above the sternal angle; an estimate of right-sided filling pressure. *(Ch. 16)*

Jurisprudence Examination: CNO's online, open-book examination on the legislation, by-laws, practice standards and guidelines that apply to Ontario nurses. *(Ch. 1)*

just culture: An organizational culture that responds to honest errors with learning and system improvement while holding people accountable for reckless choices. *(Ch. 1)*

Kaposi sarcoma: a cancer linked to human herpesvirus 8 that causes patches or nodules on the skin or in the mouth; classically violet, with colour that varies by skin tone. *(Ch. 21)*

ketones: acids made by the liver from fatty acids when insulin is lacking; beta-hydroxybutyrate is the main one in ketoacidosis *(Ch. 22)*

kidney replacement therapy (KRT): treatment that takes over the work of failed kidneys: hemodialysis, peritoneal dialysis or a kidney transplant. *(Ch. 27)*

kidney transplant: surgery to place a healthy kidney from a living or deceased donor into a person with kidney failure. *(Ch. 27)*

kindling: the tendency for each episode of alcohol withdrawal to be more severe than the last after repeated cycles of heavy drinking and withdrawal. *(Ch. 11)*

Korsakoff syndrome: a lasting memory disorder, often following untreated Wernicke encephalopathy, in which the person cannot form new memories. *(Ch. 11)*

Kussmaul breathing: deep, rapid breathing seen in metabolic acidosis. *(Ch. 12)*

Kussmaul respirations: deep, rapid breathing that removes carbon dioxide to offset a metabolic acidosis, as in DKA. *(Ch. 22)*

lactate: a product of glucose metabolism; a level above 2 mmol/L in sepsis marks greater severity and risk of death. *(Ch. 4)*

laminectomy: Surgery that removes part of the lamina, the bony arch at the back of a vertebra, to relieve pressure on the spinal cord or nerves. *(Ch. 33)*

langue des signes québécoise (LSQ): A full signed language used by many Deaf people in Quebec and French-speaking communities; recognized in the Accessible Canada Act. *(Ch. 36)*

laparoscopic cholecystectomy: Removal of the gallbladder through small abdominal incisions using a camera and instruments. *(Ch. 26)*

large vessel occlusion (LVO): A blockage of a major brain artery, which may be treated with endovascular thrombectomy. *(Ch. 31)*

laryngectomy: Surgical removal of the larynx, after which the trachea opens to the neck as an end stoma. *(Ch. 12)*

last known well (LKW): The last time a person was known to be at their usual self without the new stroke signs; used to time treatment when onset was not witnessed. *(Ch. 31)*

latex allergy: an allergic reaction to natural rubber latex, either delayed (type IV contact dermatitis) or immediate (type I, including anaphylaxis). *(Ch. 21)*

LDL cholesterol (LDL-C): cholesterol carried in low-density lipoprotein particles, reported in mmol/L; the main target of lipid-lowering treatment. *(Ch. 17)*

least restraint: Trying alternatives first and, if a restraint cannot be avoided, using the least restrictive form for the shortest possible time. *(Ch. 8)*

left ventricular assist device (LVAD): An implanted pump that moves blood from the left ventricle into the aorta in advanced heart failure. *(Ch. 18)*

left-sided heart failure: Failure of the left ventricle, raising pressure in the pulmonary veins and causing lung congestion. *(Ch. 18)*

lens: The clear structure behind the pupil that works with the cornea to focus light onto the retina. *(Ch. 36)*

leukemia: a cancer that starts in the blood-forming stem cells of the bone marrow, in which immature cells crowd out normal blood cells. *(Ch. 20)*

leukocyte esterase: An enzyme from white blood cells; a positive dipstick result suggests pyuria. *(Ch. 28)*

level of consciousness: How awake a person is (arousal) and how well the person understands self and surroundings (awareness). *(Ch. 30)*

levodopa: A medication that the brain converts to dopamine; combined with carbidopa, it is the most effective treatment for the motor symptoms of Parkinson disease. *(Ch. 32)*

licensed practical nurse (LPN): The title for a practical nurse in most Canadian provinces and territories outside Ontario. *(Ch. 1)*

lipase: A pancreatic digestive enzyme; a blood level at least three times the upper limit of normal is one of the diagnostic features of acute pancreatitis. *(Ch. 26)*

lipohypertrophy: a lump of thickened fatty tissue at an overused injection site, from which insulin is absorbed poorly and unpredictably *(Ch. 22)*

lipoprotein(a) [Lp(a)]: an inherited lipoprotein particle that adds cardiovascular risk; measured once in a lifetime. *(Ch. 17)*

live attenuated vaccine: a vaccine containing a weakened organism that can still replicate, such as MMR or varicella vaccine. *(Ch. 21)*

live vaccine: a vaccine containing a weakened form of a living microbe; generally avoided in people who are severely immunocompromised. *(Ch. 21)*

liver transplant: Replacement of a failing liver with a whole liver from a deceased donor or part of a liver from a living donor. *(Ch. 26)*

lobectomy: Surgical removal of one lobe of a lung. *(Ch. 13)*

local anesthetic systemic toxicity (LAST): a toxic reaction of the brain and heart when local anesthetic reaches a high level in the blood. *(Ch. 7)*

local infiltration: injection of local anesthetic into the tissue at the site of a minor procedure. *(Ch. 7)*

lockbox: An informal term for a patient's instruction that limits how some or all of their personal health information may be used or shared. *(Ch. 1)*

log roll: Turning a patient so that the head, shoulders, trunk and hips move together as one unit and the spine does not twist. *(Ch. 32)*

long-acting beta2-agonist (LABA): A bronchodilator that keeps airways open for many hours; in asthma it is always combined with an inhaled corticosteroid. *(Ch. 14)*

long-acting muscarinic antagonist (LAMA): A long-acting bronchodilator, such as tiotropium, used mainly in COPD and as an add-on in asthma. *(Ch. 14)*

loop ostomy: an ostomy made by bringing a loop of bowel to the surface and opening it, often as a temporary diversion. *(Ch. 25)*

low anterior resection: surgery that removes a tumour in the middle or upper rectum, usually joining the colon to the remaining rectum. *(Ch. 25)*

low vision: As used in this chapter, vision loss that cannot be fully corrected with glasses, contact lenses, medicine or surgery and that limits everyday activities. *(Ch. 36)*

low-dose buprenorphine initiation: starting buprenorphine with very small, gradually increasing doses while the usual opioid continues until an effective dose is reached; also called microdosing. *(Ch. 11)*

low-flow device: An oxygen device whose delivered concentration varies with the patient's breathing pattern, such as a nasal cannula, simple face mask or non-rebreather mask. *(Ch. 12)*

low-molecular-weight heparin (LMWH): a subcutaneous heparin, such as enoxaparin, dalteparin or tinzaparin, that acts mainly against factor Xa. *(Ch. 19)*

lower limit of normal (LLN): The value below which only 5% of healthy people fall; used to judge whether a lung function result is abnormal. *(Ch. 14)*

lower urinary tract symptoms (LUTS): voiding symptoms (weak stream, hesitancy, straining, incomplete emptying) and storage symptoms (urgency, frequency, nocturia). *(Ch. 28)*

lucid interval: A period after a head injury when the person wakes and seems well before deteriorating, typical of an epidural hematoma. *(Ch. 32)*

lumbar puncture (LP): A procedure in which a needle is passed between lower back vertebrae into the CSF space to measure pressure and collect fluid. *(Ch. 30)*

Lund and Browder chart: A body diagram used to estimate the percentage of body surface burned; the most accurate method and the preferred one for children. *(Ch. 35)*

lung-protective ventilation: Ventilation with small tidal volumes and limited pressures to avoid further injury to the lungs. *(Ch. 15)*

lupus nephritis: Inflammation of the kidneys caused by systemic lupus erythematosus. *(Ch. 34)*

lymphedema: Swelling caused by a build-up of lymph in the tissues when lymph cannot drain normally, often after lymph nodes are removed or treated with radiation. *(Ch. 29)*

lymphoma: a cancer of lymphocytes that usually grows in lymph nodes or other lymphatic tissue; the two main groups are Hodgkin and non-Hodgkin lymphoma. *(Ch. 20)*

macrocytic anemia: anemia with large red cells, typically from vitamin B12 or folate deficiency *(Ch. 20)*

macula: The central area of the retina that gives sharp central vision. *(Ch. 36)*

magnetic resonance imaging (MRI): An imaging test that uses a strong magnetic field and radio waves to make detailed images of soft tissues such as the brain and spinal cord. *(Ch. 30)*

maintenance and reliever therapy (MART): Use of one budesonide–formoterol inhaler both as the daily controller and as the reliever for symptoms. *(Ch. 14)*

malignant hyperthermia (MH): an inherited, life-threatening hypermetabolic reaction of skeletal muscle triggered by volatile anesthetic gases and succinylcholine. *(Ch. 7)*

malignant spinal cord compression: Pressure on the spinal cord or nerve roots from cancer in the spine, causing pain and possible loss of strength, sensation and bladder or bowel control. *(Ch. 9)*

malnutrition: In this chapter, undernutrition: a state in which the body does not take in or use enough energy and nutrients, so muscle and fat are lost and function declines. *(Ch. 24)*

masked hypertension: Normal blood pressure in the office with raised readings at home or on ambulatory monitoring. *(Ch. 19)*

massive hemorrhage protocol: a hospital protocol that rapidly delivers blood components to a patient with life-threatening bleeding until the bleeding is controlled. *(Ch. 6)*

massive pulmonary embolism: High-risk pulmonary embolism, in which the circulation is unstable (persistent hypotension, obstructive shock or cardiac arrest). *(Ch. 15)*

mastectomy: Surgery that removes all of the breast tissue. *(Ch. 29)*

mean arterial pressure (MAP): The average arterial pressure over one cardiac cycle, reflecting the pressure that drives blood into the organs; commonly estimated as diastolic pressure plus one third of the pulse pressure. *(Ch. 6)*

mean corpuscular volume (MCV): the average size of red blood cells, in femtolitres, used to sort anemias into small-cell, normal-cell and large-cell patterns *(Ch. 20)*

mechanical complications of MI: Rare tears in heart structures weakened by infarction, including papillary muscle rupture, ventricular septal rupture and free wall rupture. *(Ch. 17)*

mechanical lift: A device that raises and moves a person in a sling, from the floor or a ceiling track, so that staff do not bear the person's weight. *(Ch. 33)*

mechanical obstruction: a bowel obstruction caused by something that blocks, compresses or twists the bowel, such as adhesions, a hernia, a tumour or volvulus. *(Ch. 25)*

mechanical valve: A durable replacement heart valve made of synthetic materials that requires lifelong anticoagulation with warfarin. *(Ch. 18)*

mechanical ventilation: Use of a machine to move air into the lungs through an endotracheal or tracheostomy tube. *(Ch. 15)*

medical assistance in dying (MAID): Under the Criminal Code, a physician or NP either giving a person, at their request, a substance that causes death, or prescribing or providing one that the person takes themselves. *(Ch. 10)*

medical directive: An order written in advance by an authorized prescriber that applies to any patient who meets set conditions. *(Ch. 12)*

medical expulsive therapy (MET): use of a drug to help a ureteral stone pass; any benefit is for larger (5 to 10 mm) stones in the lower ureter. *(Ch. 28)*

medical-surgical nursing: The nursing care of adults who are acutely ill, living through an exacerbation of a chronic illness, or preparing for or recovering from surgery, in hospital and across other settings. *(Ch. 1)*

medication reconciliation: A structured process in which providers, patients and families make sure accurate, complete medication information goes with the patient at admission, transfer and discharge. *(Ch. 1)*

melanoma: A cancer that starts in melanocytes, the skin cells that make the pigment melanin; less common than non-melanoma skin cancer. *(Ch. 35)*

melena: black, sticky, tar-like stool containing digested blood. *(Ch. 24)*

menopausal hormone therapy: Estrogen, alone or with a progestogen, used to relieve menopause symptoms. *(Ch. 29)*

menopause: The permanent end of menstruation caused by the loss of ovarian follicles, confirmed after 12 months in a row with no period and no other cause. *(Ch. 29)*

metabolic acidosis: An acid–base disorder with a low pH caused by a primary fall in bicarbonate. *(Ch. 3)*

metabolic alkalosis: An acid–base disorder with a high pH caused by a primary rise in bicarbonate. *(Ch. 3)*

metabolic dysfunction-associated steatohepatitis (MASH): MASLD with inflammation and liver cell injury; formerly called nonalcoholic steatohepatitis (NASH). *(Ch. 26)*

metabolic dysfunction-associated steatotic liver disease (MASLD): Fat build-up in the liver with at least one cardiometabolic risk factor and no other cause; formerly called nonalcoholic fatty liver disease (NAFLD). *(Ch. 26)*

metastasis: spread of cancer from its primary site to a distant site, where it forms a new tumour. *(Ch. 9)*

methadone: a long-acting full opioid agonist used as a first-line opioid agonist treatment; its long duration of action calls for prolonged monitoring after excess doses. *(Ch. 5)*

methicillin-resistant Staphylococcus aureus (MRSA): a strain of S. aureus that resists methicillin and related antibiotics; spread mainly by contact. *(Ch. 4)*

methotrexate: The most commonly used disease-modifying drug for rheumatoid arthritis, taken once a week on a named day; daily use by mistake has caused fatal toxicity. *(Ch. 34)*

microclimate: The conditions, especially moisture and warmth, at the skin where it meets a surface such as a mattress or chair. *(Ch. 35)*

middle ear: The air-filled space behind the eardrum containing three small bones that carry sound vibrations to the inner ear. *(Ch. 36)*

midstream clean-catch specimen: A urine sample collected from the middle of the stream after the genital area is cleaned, to reduce contamination by skin bacteria. *(Ch. 28)*

mineralocorticoid receptor antagonist (MRA): A drug that blocks aldosterone, such as spironolactone or eplerenone; its main risk is hyperkalemia. *(Ch. 18)*

mitral regurgitation: Backward leakage of blood from the left ventricle into the left atrium through a mitral valve that does not close fully; primary when the valve itself is diseased and secondary when chamber enlargement pulls the leaflets apart. *(Ch. 18)*

mitral stenosis: Narrowing of the mitral valve, most often caused by rheumatic heart disease. *(Ch. 18)*

mixed delirium: delirium in which the person moves between hyperactive and hypoactive patterns. *(Ch. 8)*

mixed hearing loss: Hearing loss with both conductive and sensorineural parts. *(Ch. 36)*

Mobitz I: Second-degree AV block in which the PR interval lengthens progressively until a P wave is not conducted (also called Wenckebach). *(Ch. 16)*

Mobitz II: Second-degree AV block in which the PR interval stays constant but some P waves are suddenly not conducted. *(Ch. 16)*

modulation: the nervous system's ability to increase or decrease pain signals, largely through pathways descending from the brainstem *(Ch. 5)*

moisture balance: Keeping a healable wound moist enough for cells to migrate but not so wet that the edges macerate. *(Ch. 35)*

moisture-associated skin damage (MASD): Inflammation and erosion of skin caused by long contact with urine, stool, sweat, wound drainage or stoma output. *(Ch. 35)*

monofilament testing: a screening test of protective sensation in which a 10 g nylon filament is pressed against the foot; loss of sensation predicts ulcers and amputation. *(Ch. 22)*

moral distress: Psychological distress, such as guilt, anger or powerlessness, caused by a moral event such as a constraint, conflict, dilemma or uncertainty. *(Ch. 10)*

morning stiffness: Joint stiffness after waking; lasting 30 minutes or more suggests inflammatory arthritis, while osteoarthritis stiffness usually eases in less than 30 minutes. *(Ch. 34)*

morphine milligram equivalent (MME): a way of expressing different opioids as an equivalent amount of oral morphine, so that total opioid exposure can be compared. *(Ch. 5)*

mottling: patchy, lace-like skin discolouration, usually starting at the knees, that signals poor skin perfusion; harder to see on darker skin. *(Ch. 4)*

mu-opioid receptor: the opioid receptor most responsible for pain relief, found in pain-modulating areas of the brain and spinal cord and in the gut wall. *(Ch. 5)*

mucosal membrane pressure injury: A pressure injury on a moist lining, such as the lips or nose, where a device has been used; it cannot be staged. *(Ch. 35)*

mucositis: inflammation and ulceration of the lining of the mouth or gastrointestinal tract caused by cancer treatment. *(Ch. 9)*

multicomponent prevention: a bundle of non-drug measures, such as orientation, sensory aids, sleep, hydration, nutrition and mobility, used together to prevent delirium. *(Ch. 8)*

multimodal analgesia: the combined use of medications, procedures and non-drug measures that act on different parts of the pain pathway *(Ch. 5)*

multimorbidity: Living with two or more chronic health conditions at the same time. *(Ch. 1)*

Multinational Association for Supportive Care in Cancer (MASCC) risk index: A validated score prescribers use to estimate the risk of serious complications in febrile neutropenia. *(Ch. 9)*

multiple myeloma: a cancer of plasma cells in the bone marrow that can cause high calcium, kidney problems, anemia and bone disease. *(Ch. 20)*

multiple sclerosis (MS): A chronic autoimmune disease in which the immune system damages myelin in the optic nerves, brain and spinal cord. *(Ch. 32)*

murmur: A heart sound made by turbulent blood flow, described by its timing, location, loudness and quality. *(Ch. 16)*

Murphy sign: A sudden stop in breathing in, caused by pain, when the examiner presses under the right rib margin; a local sign of acute cholecystitis. *(Ch. 26)*

myasthenia gravis (MG): An autoimmune disease in which antibodies block signals at the neuromuscular junction, causing weakness that worsens with use and improves with rest. *(Ch. 32)*

myasthenic crisis: MG weakness that worsens until the person needs intubation, or noninvasive ventilation to prevent intubation. *(Ch. 32)*

myelin: The fatty covering that insulates nerve fibres and lets signals travel quickly. *(Ch. 32)*

myelosuppression: reduced production of blood cells by the bone marrow, causing neutropenia, anemia and thrombocytopenia. *(Ch. 9)*

myocardial infarction (MI): death of heart muscle cells from ischemia, shown by a rise and/or fall in cardiac troponin with at least one value above the 99th percentile plus clinical evidence of ischemia. *(Ch. 17)*

myocarditis: Inflammation of the heart muscle. *(Ch. 18)*

myxedema coma: The most severe form of hypothyroidism, an emergency with a falling level of consciousness, hypothermia, bradycardia, hypoventilation and low sodium. *(Ch. 23)*

Ménière disease: An inner ear disorder with vertigo attacks, each 20 minutes to 12 hours long, with sensorineural hearing loss, tinnitus and a feeling of fullness in the affected ear. *(Ch. 36)*

Métis: A distinct Indigenous People who emerged from the 18th-century fur trade, with their own culture, language (Michif) and nationhood; being Métis is not the same as having mixed ancestry. *(Ch. 2)*

N-acetylcysteine (NAC): The antidote for acetaminophen overdose (marketed in Canada as acetylcysteine), given whenever overdose is suspected, even if the timing is unknown. *(Ch. 26)*

N95 respirator: A close-fitting respirator that filters 95% of particles about 1 micron in size; it must be fit-tested and seal-checked. *(Ch. 4)*

nadir: the lowest point that a blood count reaches after a cancer treatment. *(Ch. 9)*

naloxone: an opioid antagonist that reverses opioid effects, including respiratory depression. *(Ch. 5)*

nasal cannula: Two short prongs in the nostrils that deliver low-flow oxygen; the most common oxygen device. *(Ch. 12)*

nasogastric (NG) tube: A tube passed through the nose and esophagus into the stomach, used for short-term feeding, medications or drainage. *(Ch. 24)*

nasogastric decompression: drainage of swallowed air and gastrointestinal fluid through a nasogastric tube to relieve distension and vomiting. *(Ch. 25)*

nasopharyngeal airway: A soft tube passed through a nostril into the pharynx to keep the upper airway open. *(Ch. 12)*

National Overdose Response Service (NORS): a confidential national phone and text line that provides overdose response for people who use drugs alone. *(Ch. 11)*

natriuretic peptide: A hormone (BNP or NT-proBNP) released by heart muscle under increased wall stress; used in assessing heart failure. *(Ch. 16)*

natriuretic peptides: Hormones (ANP and BNP) released by stretched heart muscle that increase sodium and water excretion and oppose the renin–angiotensin–aldosterone system. *(Ch. 3)*

near miss: A patient safety incident that did not reach the patient. *(Ch. 1)*

nebulizer: A device that turns liquid medicine into a mist breathed in through a mouthpiece or mask. *(Ch. 14)*

neck breather: A person who breathes only through a neck stoma after laryngectomy and cannot be oxygenated or ventilated through the mouth or nose. *(Ch. 12)*

neck hematoma: A collection of blood under a neck incision that can compress the airway; an emergency after thyroid or parathyroid surgery. *(Ch. 23)*

necrotizing soft tissue infection: A rapidly spreading infection that destroys deep tissues such as fat and fascia; a surgical emergency. *(Ch. 35)*

negative feedback: The control loop in which a rising level of a final hormone reduces release of the hormones that stimulate it, and a falling level increases their release. *(Ch. 23)*

negative pressure wound therapy: Wound treatment that uses a sealed dressing connected to a pump that applies suction to the wound. *(Ch. 35)*

neglect: A disorder in which a person does not attend to one side of space or of their own body, most often the left side after a right hemisphere stroke. *(Ch. 31)*

neoadjuvant therapy: treatment given before surgery to shrink a tumour. *(Ch. 9)*

nephron: one of about a million filtering units in each kidney, made up of a glomerulus and a tubule *(Ch. 27)*

nephrostomy tube: a tube placed through the skin of the back into the kidney to drain urine. *(Ch. 28)*

nephrotoxic: able to damage the kidneys, as some drugs and contrast agents can *(Ch. 27)*

neuraxial anesthesia: anesthesia produced by placing local anesthetic near the spinal cord, as in spinal and epidural anesthesia. *(Ch. 7)*

neurogenic shock: low blood pressure with a slow heart rate after a cervical or high-thoracic spinal cord injury, caused by loss of sympathetic tone. *(Ch. 6)*

neuromuscular junction: The site where a motor nerve passes its signal to a muscle fibre. *(Ch. 32)*

neuron: A nerve cell that receives, processes and sends signals; it has a cell body, dendrites and an axon. *(Ch. 30)*

neuropathic pain: pain resulting from damage to, or disease of, the nerves that carry sensation *(Ch. 5)*

neurovascular assessment: A check of blood flow and nerve function in a limb below an injury, cast, splint, bandage or surgical site. *(Ch. 33)*

NEWS2: The National Early Warning Score 2 (Royal College of Physicians, 2017), which scores respiratory rate, oxygen saturation, supplemental oxygen, systolic blood pressure, pulse, level of consciousness (including new confusion) and temperature. *(Ch. 6)*

Next Generation NCLEX (NGN): The version of the NCLEX, launched in April 2023, that uses case studies and new item formats to measure clinical judgment. *(Ch. 1)*

nicotine replacement therapy (NRT): Medication that supplies nicotine without tobacco smoke, as a patch or short-acting forms such as gum and lozenges, to ease withdrawal and cravings. *(Ch. 14)*

nimodipine: A medicine given by the enteral route after aneurysmal subarachnoid hemorrhage to help prevent delayed cerebral ischemia. *(Ch. 31)*

nitrites: Chemicals formed when certain bacteria convert nitrate in urine; a negative result does not rule out bacteriuria. *(Ch. 28)*

no-harm incident: A patient safety incident that reached the patient without detectable harm. *(Ch. 1)*

nociception: the nervous system's process of detecting and encoding harmful stimuli; it is not the same as pain *(Ch. 5)*

nociceptive pain: pain from actual or threatened damage to tissue other than nerves, with a normally working nervous system *(Ch. 5)*

nociceptor: a sensory nerve ending that responds to strong heat, pressure or chemical stimuli and converts them into nerve signals *(Ch. 5)*

nociplastic pain: pain from altered pain processing without clear tissue damage or nerve disease to explain it *(Ch. 5)*

nocturia: waking at night to pass urine. *(Ch. 28)*

non-HDL cholesterol (non-HDL-C): total cholesterol minus HDL cholesterol; the cholesterol in all atherogenic particles. *(Ch. 17)*

Non-Insured Health Benefits (NIHB): An Indigenous Services Canada program that covers specified health benefits, including medical transportation, for registered First Nations and recognized Inuit when other plans do not. *(Ch. 1)*

non-invasive ventilation: Breathing support delivered through a tight-fitting mask rather than a tube in the airway. *(Ch. 15)*

non-rebreather mask: A face mask with a reservoir bag, run at 15 L/min, that delivers a high oxygen concentration to a seriously ill patient. *(Ch. 12)*

non-small cell lung cancer (NSCLC): The group of lung cancers other than small cell, including adenocarcinoma, squamous cell carcinoma and large cell carcinoma. *(Ch. 13)*

noncardiogenic pulmonary edema: Fluid in the alveoli caused by leaky lung capillaries rather than by heart failure or fluid overload. *(Ch. 15)*

noninvasive ventilation (NIV): Breathing support given through a mask rather than a tube in the airway. *(Ch. 32)*

nonsteroidal anti-inflammatory drug (NSAID): a drug that reduces pain and inflammation by blocking cyclooxygenase enzymes *(Ch. 5)*

nonunion: A fracture that fails to heal. *(Ch. 33)*

normal sinus rhythm: A regular rhythm from the SA node at 60 to 100 bpm, with an upright P wave before each QRS, a PR interval of 0.12 to 0.20 seconds and a QRS under 0.12 seconds. *(Ch. 16)*

NSTEMI (non-ST-elevation myocardial infarction): an MI confirmed by troponin without persistent ST elevation on the ECG. *(Ch. 17)*

nucleic acid amplification test: A laboratory test that detects an organism's genetic material; the most sensitive test for chlamydia and gonorrhea. *(Ch. 29)*

nucleic acid amplification test (NAAT): A rapid laboratory test that detects the genetic material of M. tuberculosis in a specimen and can identify rifampin resistance. *(Ch. 13)*

numeric rating scale (NRS): a self-report scale on which the patient rates pain from 0 (no pain) to 10 (worst pain imaginable) *(Ch. 5)*

Nurse Specialized in Wound, Ostomy and Continence (NSWOC): a registered nurse with advanced education and clinical skills in wound, ostomy and continence care. *(Ch. 25)*

nurse-driven catheter removal protocol: A protocol, often a medical directive, that lets nurses remove a urinary catheter when no listed indication remains. *(Ch. 28)*

NYHA functional class: A four-level scale describing how much heart failure symptoms limit activity. *(Ch. 18)*

obesity: a chronic, complex disease in which excess or abnormal body fat harms health. *(Ch. 24)*

obstructive lung disease: Lung disease in which narrowed airways slow the flow of air out of the lungs and trap air, as in asthma and COPD. *(Ch. 14)*

obstructive shock: Shock caused by a physical blockage of blood flow into or out of the heart, as in pulmonary embolism, cardiac tamponade or tension pneumothorax. *(Ch. 6)*

obstructive sleep apnea (OSA): Repeated collapse of the upper airway during sleep that interrupts breathing. *(Ch. 7)*

obturator: A rounded guide placed inside a tracheostomy tube during insertion; kept at the bedside. *(Ch. 12)*

OCAP®: The First Nations principles of Ownership, Control, Access and Possession, which state that First Nations govern data about their communities; a registered trademark of the First Nations Information Governance Centre. *(Ch. 2)*

occult hypoxemia: Low arterial oxygen saturation (below 88%) that is hidden by a pulse oximeter reading in the normal-looking range (92% to 96%). *(Ch. 2)*

offloading: Removing pressure from an area of the body completely, for example by floating the heels off the bed. *(Ch. 35)*

oliguria: an abnormally low urine output *(Ch. 27)*

oncologic emergency: A sudden, life-threatening problem caused by cancer or its treatment that needs immediate recognition and action. *(Ch. 9)*

Ontario Health Team: A group of local providers, such as hospitals, primary care, home and community care and long-term care, that plans and delivers connected care for patients in a local area of Ontario. *(Ch. 1)*

open fracture: A fracture in which the bone breaks through the skin or a wound connects with the break, allowing bacteria to reach the bone. *(Ch. 33)*

open-angle glaucoma: A slowly progressive form of glaucoma that typically causes no symptoms until it is advanced. *(Ch. 36)*

opioid: a drug that acts on the body's opioid receptors to relieve pain; adverse effects include sedation, respiratory depression and constipation. *(Ch. 5)*

opioid agonist treatment (OAT): treatment of opioid use disorder with a long-acting opioid, such as methadone or buprenorphine, that prevents withdrawal and cravings. *(Ch. 5)*

opioid toxicity: a life-threatening depression of breathing and consciousness caused by opioids; often called an opioid overdose or poisoning. *(Ch. 11)*

opioid use disorder (OUD): a problematic pattern of opioid use causing significant problems or distress, diagnosed when at least 2 of 11 criteria occur within a year. *(Ch. 5)*

opioid withdrawal: the symptoms that follow stopping or sharply reducing opioids in a person who is physically dependent on them. *(Ch. 11)*

opioid-induced respiratory depression (OIRD): reduced drive and effort to breathe caused by an opioid, leading to carbon dioxide build-up and possibly respiratory arrest; usually preceded by increasing sedation. *(Ch. 5)*

opioid-naive: describes a patient who has not been taking opioids regularly. *(Ch. 5)*

opportunistic infection: an infection that takes advantage of a weakened immune system. *(Ch. 21)*

optic nerve: The nerve that carries signals from the retina to the brain. *(Ch. 36)*

organ inventory: A respectful record of the reproductive and sex organs a person has at present, used to guide screening and care without assumptions based on gender. *(Ch. 29)*

orolingual angioedema: Swelling of the lips, tongue or throat that can follow thrombolysis and threaten the airway. *(Ch. 31)*

oropharyngeal airway: A curved device placed in the mouth to hold the tongue off the back of the throat in a patient with a markedly reduced level of consciousness. *(Ch. 12)*

orthopnea: Breathlessness when lying flat that eases on sitting up. *(Ch. 18)*

orthostatic hypotension: A fall in systolic blood pressure of at least 20 mm Hg, or diastolic of at least 10 mm Hg, within 3 minutes of standing. *(Ch. 3)*

osmolality: The concentration of dissolved particles per kilogram of water, reported in mOsm/kg. *(Ch. 3)*

osmolarity: The concentration of dissolved particles per litre of solution, reported in mOsmol/L. *(Ch. 3)*

osmosis: Movement of water across a membrane from an area of lower to higher solute concentration. *(Ch. 3)*

osmotherapy: The use of a concentrated solution, such as mannitol or hypertonic saline, to draw water out of brain tissue and lower intracranial pressure. *(Ch. 30)*

osmotic demyelination syndrome (ODS): Damage to the myelin of brain nerve fibres caused by too rapid a rise in serum sodium in chronic hyponatremia. *(Ch. 3)*

osteoarthritis (OA): A progressive disease of the whole joint in which cartilage and underlying bone break down; the most common type of arthritis in Canada. *(Ch. 34)*

osteomyelitis: Infection of the bone. *(Ch. 33)*

osteoporosis: A disease in which bones lose mass and strength and break more easily. *(Ch. 33)*

ostomy: a surgically created opening into the bowel or urinary tract through which stool or urine leaves the body. *(Ch. 25)*

otitis externa: Infection or inflammation of the ear canal, often after water is trapped in the ear; pain worsens when the outer ear is tugged. *(Ch. 36)*

otitis media: Infection or fluid in the middle ear, listed mainly as a cause of hearing loss in childhood; it causes a conductive hearing loss. *(Ch. 36)*

ototoxicity: Damage to the inner ear, affecting hearing, balance or both, caused by a medicine or chemical. *(Ch. 36)*

Ottawa Model for Smoking Cessation: A hospital program that identifies every patient who smokes, provides bedside counselling and medication, and follows patients after discharge. *(Ch. 14)*

outbreak: A rise in cases of an infection above what is expected in a particular place and time, defined for each infection. *(Ch. 4)*

outer ear: The visible ear and the ear canal, ending at the eardrum. *(Ch. 36)*

outpatient parenteral antibiotic therapy (OPAT): Intravenous antibiotic treatment given outside hospital, at home or in a clinic. *(Ch. 18)*

overdiagnosis: detection through screening of a cancer that would never have caused symptoms or death. *(Ch. 9)*

overflow diarrhea: Liquid stool that leaks around a fecal impaction and can be mistaken for ordinary diarrhea. *(Ch. 25)*

overflow incontinence: Leakage from a bladder that overfills because it cannot empty. *(Ch. 28)*

oxygen target range: The SpO2 range the prescriber orders, within which the nurse adjusts oxygen. *(Ch. 12)*

oxygen–hemoglobin dissociation curve: the S-shaped curve relating PaO2 to hemoglobin saturation; flat above about 90% saturation and steep below a PaO2 of about 60 mm Hg. *(Ch. 12)*

P wave: The ECG wave produced by atrial depolarization. *(Ch. 16)*

P/F ratio: The ratio of arterial oxygen pressure (PaO2) to the fraction of inspired oxygen (FiO2), used to grade the severity of hypoxemia and ARDS. *(Ch. 15)*

P2Y12 inhibitor: A drug that blocks the P2Y12 receptor on platelets so they are less able to clump; clopidogrel, ticagrelor and prasugrel are examples. *(Ch. 17)*

$PaCO_2$: The partial pressure of carbon dioxide in arterial blood, the respiratory component of an ABG. *(Ch. 3)*

pain: an unpleasant sensory and emotional experience linked to, or resembling one linked to, actual or potential tissue damage (IASP definition, 2020) *(Ch. 5)*

Pain Assessment in Advanced Dementia (PAINAD) scale: an observational tool scoring five behaviours from 0 to 10 for people living with advanced dementia who cannot self-report *(Ch. 5)*

pain sensitization: A state in which the nervous system amplifies pain signals, so pain is felt more strongly than tissue changes alone would explain. *(Ch. 34)*

palliative approach: The integration of core palliative care principles into everyday care by all providers, early in a serious illness and in every setting, with specialists supporting complex needs. *(Ch. 10)*

palliative care: Care that aims to prevent and relieve suffering and improve quality of life for people who have a life-limiting illness and for those close to them, from diagnosis onward. *(Ch. 10)*

palliative sedation: The closely monitored use of medications to reduce consciousness, in proportion to need, so as to relieve refractory suffering in a person with a life-limiting disease. *(Ch. 10)*

palmar erythema: Redness of the palms, mostly at the base of the thumb and little finger, seen in advanced liver disease. *(Ch. 26)*

pancreatic enzyme replacement therapy (PERT): Capsules of pancreatic enzymes taken with meals and snacks to digest food when the pancreas no longer makes enough enzymes. *(Ch. 26)*

papillary muscle rupture: A tear in a muscle that anchors the mitral valve, causing sudden severe mitral leakage after MI. *(Ch. 17)*

paracentesis: Drainage of ascitic fluid through a needle or catheter in the abdominal wall, for diagnosis or to relieve a large or tense ascites. *(Ch. 26)*

paralytic ileus: a loss of the bowel's propulsive movement without any physical blockage, causing gas and fluid to build up. *(Ch. 25)*

paraneoplastic syndrome: Signs and symptoms caused by substances a tumour releases, such as hormones, rather than by the tumour's direct spread. *(Ch. 13)*

paraplegia: Weakness or paralysis of the trunk, legs or both, sparing the arms, from an injury below the cervical cord. *(Ch. 32)*

parastomal hernia: a bulge of abdominal contents through the abdominal wall opening around a stoma. *(Ch. 25)*

parathyroid hormone (PTH): The hormone from the parathyroid glands that raises blood calcium through bone, the kidneys and activated vitamin D. *(Ch. 23)*

parathyroid hormone–related peptide (PTHrP): A substance released by some tumours that increases bone breakdown and raises blood calcium. *(Ch. 9)*

parathyroidectomy: Surgical removal of one or more overactive parathyroid glands. *(Ch. 23)*

parenteral nutrition: Nutrition given into a vein, used when the gut cannot be used or cannot meet the person's needs. *(Ch. 24)*

Parkinson disease (PD): A chronic, progressive neurologic disease marked by tremor, rigidity, slow movement and poor balance, with many non-motor symptoms. *(Ch. 32)*

paroxysmal nocturnal dyspnea (PND): Waking from sleep suddenly short of breath and needing to sit up. *(Ch. 18)*

partial agonist: a drug, such as buprenorphine, that activates the mu receptor less fully than a full agonist. *(Ch. 5)*

partial-thickness burn: A burn that destroys the epidermis and part of the dermis; superficial partial-thickness burns blister and are very painful, and deep partial-thickness burns usually need surgery. *(Ch. 35)*

partner notification: The process of informing sexual partners of a possible exposure so they can be tested and treated. *(Ch. 29)*

pathologic fracture: A fracture through bone already weakened by disease, such as a tumour that has spread to bone. *(Ch. 33)*

patient safety incident: An event or circumstance that led to, or could have led to, unnecessary harm to a patient. *(Ch. 1)*

patient- and family-centred care: An approach to planning, giving and evaluating care built on partnership among patients, the people they define as family, and health care providers. *(Ch. 1)*

patient-controlled analgesia (PCA): a programmable pump that lets a patient give themselves set doses of analgesic, limited by a lockout interval. *(Ch. 5)*

PAWSS: the Prediction of Alcohol Withdrawal Severity Scale; a 10-item tool that estimates a hospitalized patient's risk of complicated alcohol withdrawal. *(Ch. 11)*

PCA by proxy: unauthorized pressing of a PCA button by someone other than the patient, which bypasses the pump's safety check. *(Ch. 5)*

PDE5 inhibitor: A drug that blocks phosphodiesterase type 5 to improve erections, such as sildenafil, tadalafil or vardenafil; contraindicated with nitrates. *(Ch. 29)*

PE response team (PERT): A group of specialists who advise on treatment choices when pulmonary embolism is intermediate or high risk. *(Ch. 15)*

peak expiratory flow (PEF): The fastest speed of air during a short, sharp blow into a hand-held meter. *(Ch. 14)*

pelvic floor muscle training (PFMT): Repeated, correctly performed contractions of the pelvic floor muscles to improve continence. *(Ch. 28)*

pelvic inflammatory disease: Infection of the uterus, fallopian tubes and nearby pelvic structures, often a complication of chlamydia or gonorrhea. *(Ch. 29)*

pelvic organ prolapse: Descent of the bladder, uterus, top of the vagina or rectum into or beyond the vaginal opening because their supports have weakened. *(Ch. 29)*

penumbra: Brain tissue around the ischemic core that has stopped working but can recover if blood flow returns in time. *(Ch. 31)*

peptic ulcer disease (PUD): a break through the lining of the stomach or duodenum, most often caused by H. pylori or NSAIDs. *(Ch. 24)*

perception: the point at which a person becomes aware of pain, involving areas of the brain for sensation, emotion and thinking *(Ch. 5)*

percutaneous coronary intervention (PCI): A catheter procedure that opens a narrowed or blocked coronary artery, usually with a balloon and a stent. *(Ch. 17)*

percutaneous endoscopic gastrostomy (PEG): A gastrostomy tube placed with the help of an endoscope passed through the mouth into the stomach. *(Ch. 24)*

perforation: erosion of an ulcer through the wall of the stomach or duodenum, letting contents leak into the abdomen; a surgical emergency. *(Ch. 24)*

perfusion: blood flow through the capillaries of the lungs. *(Ch. 12)*

pericardial effusion: An abnormal collection of fluid in the pericardial sac. *(Ch. 18)*

pericardial friction rub: A scratching or grating sound produced by inflamed pericardial layers rubbing together. *(Ch. 18)*

pericardiocentesis: Removal of fluid from the pericardial sac with a needle. *(Ch. 18)*

pericarditis: Inflammation of the pericardium. *(Ch. 18)*

perimenopause: The transition before menopause, when periods change and symptoms often begin; it can start 4 to 8 years before the final period and includes the 12 months after it. *(Ch. 29)*

perioperative nursing: Nursing care given across the whole surgical experience, from the decision to operate through recovery. *(Ch. 7)*

peripheral arterial disease (PAD): narrowing or blockage of the arteries that supply the limbs, usually from atherosclerosis. *(Ch. 19)*

peripheral cyanosis: a bluish colour limited to the fingers, toes or nail beds, usually from slow peripheral blood flow. *(Ch. 12)*

peripheral nerve block: injection of local anesthetic near a nerve or group of nerves that supply one limb or area. *(Ch. 7)*

peripheral neuropathy: nerve damage from prolonged high glucose, mainly in the feet and legs, causing numbness, tingling, pain or loss of protective sensation. *(Ch. 22)*

peripheral sensitization: increased responsiveness of nerve endings near damaged tissue, so they fire more easily *(Ch. 5)*

periprosthetic joint infection: An infection of an artificial joint and the tissue around it. *(Ch. 33)*

peristalsis: Waves of muscle contraction that move food along the GI tract. *(Ch. 24)*

peristomal skin: the skin around a stoma, which should look like the person's skin elsewhere on the abdomen. *(Ch. 25)*

peritoneal dialysis (PD): dialysis at home that uses the peritoneum as the filter, with dialysate drained in and out through an abdominal catheter. *(Ch. 27)*

peritonitis: inflammation of the lining of the abdominal cavity. *(Ch. 24)*

peritonitis (PD-related): infection of the peritoneum in a person on peritoneal dialysis, signalled by cloudy effluent and abdominal pain. *(Ch. 27)*

permanent pacemaker: An implanted device with a pulse generator and leads that senses the heart's activity and paces when the rate is too slow. *(Ch. 16)*

pernicious anemia: an autoimmune disease in which loss of intrinsic factor prevents absorption of vitamin B12 *(Ch. 20)*

person-centred care: care built on knowing the patient as a whole person, honouring their choices and sharing decisions with them and those close to them. *(Ch. 8)*

person-first language: wording that names the person before a condition, such as "person who uses drugs." *(Ch. 11)*

personal amplifier: A small handheld device that makes nearby speech louder through headphones or earphones for a person with hearing loss. *(Ch. 36)*

personal directive: In Alberta, a legal document naming an agent who will make personal decisions that are not financial; it takes effect only after the person is found to lack capacity. *(Ch. 10)*

personal protective equipment (PPE): Clothing and equipment, such as gloves, gowns, masks, respirators and eye protection, that form a barrier between the provider and infectious material. *(Ch. 4)*

personal support worker (PSW): In Ontario, the most common unregulated care provider; PSWs may register voluntarily with the Health and Supportive Care Providers Oversight Authority, which sets no scope of practice. *(Ch. 1)*

pessary: A removable device placed in the vagina to support prolapsed pelvic organs. *(Ch. 29)*

petechiae: tiny, flat, red or purple pinpoint spots caused by bleeding under the skin. *(Ch. 20)*

phantom limb pain: Pain felt in the part of a limb that has been removed. *(Ch. 33)*

pheochromocytoma: a catecholamine-secreting tumour of the adrenal medulla that can cause episodes of high blood pressure, headache, palpitations and sweating. *(Ch. 23)*

phlebitis: Inflammation of a vein, often related to IV therapy. *(Ch. 3)*

photosensitivity: An abnormal skin reaction, such as a rash, after exposure to sunlight. *(Ch. 34)*

physical dependence: the body's adaptation to a drug, so that stopping suddenly or reducing the dose quickly causes withdrawal. *(Ch. 5)*

physiological reserve: the spare capacity that body systems draw on when illness, surgery or other stress adds strain. *(Ch. 8)*

pin-site care: The cleaning and dressing of the skin where external fixator or traction pins enter the body. *(Ch. 33)*

pituitary adenoma: a benign tumour of the pituitary gland that may secrete a hormone, press on nearby structures, or both. *(Ch. 23)*

plaque rupture: a tear in the fibrous cap of a plaque that exposes its core to blood and triggers thrombus formation. *(Ch. 17)*

plasma protein product: a drug made from pooled donor plasma or by recombinant technology, such as albumin, IVIG, PCC or a factor concentrate. *(Ch. 20)*

plateau pressure: The pressure in the alveoli measured during a brief pause at the end of inspiration. *(Ch. 15)*

pleural effusion: An abnormal collection of fluid in the pleural space. *(Ch. 13)*

pleural friction rub: a grating or creaking sound in both phases of breathing, caused by inflamed pleural layers rubbing together. *(Ch. 12)*

pleuritic chest pain: sharp chest pain that worsens with deep breathing or coughing, caused by inflammation of the pleura. *(Ch. 13)*

pleuritic pain: Sharp chest pain that worsens with breathing in. *(Ch. 15)*

Pneumocystis pneumonia (PJP): a fungal lung infection that causes gradually worsening breathlessness, fever, dry cough and hypoxemia in people with low CD4 counts. *(Ch. 21)*

pneumonia: an acute infection of the lung tissue (alveoli and smallest airways) that causes inflammation and fills air spaces with fluid and cells. *(Ch. 13)*

Pneumonia Severity Index (PSI): a pneumonia prediction rule that sorts patients into five risk classes using age, coexisting diseases, vital signs and laboratory values. *(Ch. 13)*

pneumothorax: Air in the pleural space, which causes part or all of the lung to collapse. *(Ch. 15)*

point-of-care glucose testing: bedside measurement of capillary glucose with a meter approved and quality-checked under hospital policy *(Ch. 22)*

point-of-care risk assessment (PCRA): A check made before every patient interaction of the task, the patient and the environment to judge the risk of transmission and choose the right precautions. *(Ch. 4)*

polymyalgia rheumatica: An inflammatory condition of adults aged 50 and older that causes aching and stiffness of the shoulders and hips. *(Ch. 34)*

polypharmacy: The use of many medications at the same time, most often defined as five or more medications daily. *(Ch. 8)*

portal hypertension: Raised pressure in the portal vein system, usually caused by resistance to blood flow through a scarred liver. *(Ch. 26)*

portal vein: The vein that carries blood from the stomach, intestines, pancreas and spleen to the liver. *(Ch. 26)*

positive end-expiratory pressure: Pressure kept in the lungs at the end of each breath to stop alveoli from collapsing. *(Ch. 15)*

positive expiratory pressure (PEP) device: A device that makes the patient breathe out against resistance to help hold airways open; oscillating versions add vibration. *(Ch. 12)*

post-COVID-19 condition: in the WHO definition, symptoms that continue more than 3 months after SARS-CoV-2 infection, last at least 2 months and have no other explanation. *(Ch. 13)*

post-exposure prophylaxis (PEP): a 28-day course of antiretroviral drugs started as soon as possible, and within 72 hours, after a possible exposure to HIV. *(Ch. 21)*

post-fall assessment: A structured assessment after a fall to find injuries, including delayed ones, and the causes of the fall. *(Ch. 8)*

post-fall huddle: A short team meeting held soon after a fall to work out why it happened and change the plan to prevent another. *(Ch. 8)*

post-ictal state: The recovery period after a seizure, when the person may be drowsy or confused. *(Ch. 30)*

post-intensive care syndrome: New or worse physical, cognitive or mental health problems that begin after critical illness and last beyond the hospital stay. *(Ch. 15)*

post-intensive care syndrome–family: Anxiety, acute or posttraumatic stress, depression or complicated grief in family members of a critically ill patient. *(Ch. 15)*

post-mastectomy pain syndrome: Nerve pain in the chest, armpit or arm that persists after healing from breast surgery. *(Ch. 29)*

post-sepsis syndrome: lasting physical, cognitive and psychological problems after surviving sepsis. *(Ch. 4)*

post-stroke depression: Depression that develops after a stroke; about one-third of people show symptoms at some point. *(Ch. 31)*

post-thrombotic syndrome (PTS): lasting pain, swelling, heaviness and skin changes in a leg after DVT. *(Ch. 19)*

post-traumatic amnesia: A stage of recovery after TBI in which awareness is poor and fluctuates, the person is disoriented and new events are not reliably remembered. *(Ch. 32)*

post-void residual (PVR): The volume of urine left in the bladder right after voiding. *(Ch. 28)*

postanesthesia care unit (PACU): A unit that gives short-term, closely monitored care immediately after operations and invasive procedures. *(Ch. 7)*

postherpetic neuralgia: Pain lasting more than 30 days after the rash of herpes zoster begins. *(Ch. 35)*

postoperative: The phase from admission to the recovery area until the patient has recovered. *(Ch. 7)*

postoperative ileus: a temporary slowing of bowel movement after surgery. *(Ch. 7)*

postoperative nausea and vomiting (PONV): nausea, retching or vomiting after anesthesia and surgery. *(Ch. 7)*

postoperative urinary retention: inability to empty a full bladder after surgery. *(Ch. 7)*

postrenal acute kidney injury: AKI caused by blocked outflow of urine *(Ch. 27)*

post–dural puncture headache: A headache that starts in the 5 days after a lumbar puncture, caused by CSF leaking through the puncture, often worse upright and better lying down. *(Ch. 30)*

potentially inappropriate medication (PIM): A drug that, for most older adults, is ineffective, carries an unnecessarily high risk or has a safer alternative. *(Ch. 8)*

pouching system: the skin barrier and pouch that protect the skin and collect stoma output; one-piece or two-piece. *(Ch. 25)*

power of attorney for personal care: In Ontario, a legal document under the Substitute Decisions Act, 1992 that names an attorney to make personal care decisions, including health care, if the person becomes incapable. *(Ch. 10)*

PR interval: The time from the start of the P wave to the start of the QRS complex; normally 0.12 to 0.20 seconds. *(Ch. 16)*

pre-emptive transplant: a kidney transplant done before dialysis has started. *(Ch. 27)*

pre-exposure prophylaxis (PrEP): antiretroviral medication taken by an HIV-negative person before possible exposure to prevent HIV. *(Ch. 21)*

precipitated withdrawal: sudden, often severe withdrawal triggered when naloxone or buprenorphine displaces a full opioid agonist from its receptors. *(Ch. 11)*

prediabetes: impaired fasting glucose, impaired glucose tolerance or an A1C of 6.0% to 6.4%; a high risk of developing diabetes *(Ch. 22)*

predicted body weight: A weight calculated from height and sex and used to set tidal volume. *(Ch. 15)*

prehabilitation: Improving physical and mental fitness in the weeks before surgery to build reserve for recovery. *(Ch. 7)*

preload: how much the ventricle is filled and stretched before it contracts. *(Ch. 6)*

premature ventricular contraction (PVC): An early beat that starts in the ventricles, seen as a wide, oddly shaped QRS with no P wave before it. *(Ch. 16)*

preoperative: The phase from the decision to operate until transfer to the operating room. *(Ch. 7)*

prerenal acute kidney injury: AKI caused by reduced blood flow to the kidneys *(Ch. 27)*

presbycusis: Age-related sensorineural hearing loss that starts at the highest pitches and later spreads to lower ones. *(Ch. 36)*

prescribing cascade: A sequence in which an adverse drug effect is mistaken for a new condition and treated with another drug. *(Ch. 8)*

pressure injury: Localized damage to skin and underlying soft tissue, usually over a bony prominence or under a device, caused by pressure or pressure combined with shear. *(Ch. 35)*

pressurized metered-dose inhaler (pMDI): A device that releases a measured puff of medicine in a propellant spray. *(Ch. 14)*

pretest probability: the estimated likelihood of a disease before testing, used to choose the testing path. *(Ch. 19)*

priapism: A prolonged erection not linked to sexual desire; an erection lasting more than 4 hours is an emergency. *(Ch. 29)*

primary aldosteronism: Excess aldosterone production by the adrenal glands, a cause of secondary hypertension. *(Ch. 19)*

primary brain injury: Damage that occurs at the moment of impact or sudden acceleration and deceleration. *(Ch. 32)*

primary brain tumour: A tumour that starts in the brain or its coverings, as opposed to one that spreads to the brain from elsewhere. *(Ch. 30)*

primary hyperparathyroidism: Excess PTH from one or more parathyroid glands, most often a single benign adenoma, causing high calcium. *(Ch. 23)*

primary hypertension: Hypertension without a single identifiable cause. *(Ch. 19)*

primary intention: Healing of a wound whose edges have been brought together with sutures, staples or tape, without the need to fill with granulation tissue. *(Ch. 35)*

primary PCI: emergency coronary angiography with balloon and stent opening of a blocked artery, without fibrinolysis first. *(Ch. 17)*

primary spontaneous pneumothorax: A pneumothorax in a person with no known lung disease. *(Ch. 15)*

principle of double effect: The ethical principle that an act aimed at a good effect may be acceptable even if a harmful effect is foreseen but not intended, provided the harm is not how the good is achieved and the act is proportionate. *(Ch. 10)*

procalcitonin: A blood marker used with clinical assessment when the likelihood of bacterial infection is uncertain and to help decide when antibiotics can be stopped. *(Ch. 4)*

procedural sedation: the use of drugs to depress consciousness so a patient can tolerate a procedure, on a continuum from minimal to deep sedation. *(Ch. 7)*

professional boundaries: The limits that keep a nurse-patient relationship therapeutic rather than personal; keeping them is always the nurse's responsibility. *(Ch. 1)*

professional interpreter: A trained interpreter who conveys health information accurately and confidentially between languages; preferred over family members. *(Ch. 1)*

progressive (decompensated) shock: The stage of shock in which compensation fails, blood pressure falls and organ hypoperfusion becomes evident. *(Ch. 6)*

progressive multifocal leukoencephalopathy (PML): A rare, serious brain infection caused by the JC virus; a risk with some immune-modifying drugs such as natalizumab. *(Ch. 32)*

prolactinoma: a prolactin-secreting pituitary adenoma, the most common type, usually treated first with a dopamine agonist. *(Ch. 23)*

prolonged grief disorder: A DSM-5-TR diagnosis of intense, disabling grief lasting at least 12 months after a death in adults (6 months in children and adolescents) and exceeding cultural norms. *(Ch. 10)*

prompted voiding: A toileting approach for frail or cognitively impaired people in which staff check regularly, ask about the need to void, help to the toilet and give praise. *(Ch. 28)*

pronator drift: A sign of subtle arm weakness in which one outstretched arm, held palm up with the eyes closed, turns palm-down and drifts downward. *(Ch. 30)*

prone positioning: Placing a ventilated patient face down for long periods to improve gas exchange in severe ARDS. *(Ch. 15)*

pronouncement of death: Determining and recording that a person has died; distinct from certifying the cause of death on the medical certificate of death. *(Ch. 10)*

prostate-specific antigen (PSA): a protein made by the prostate and measured in a blood test, used in prostate cancer screening and follow-up. *(Ch. 28)*

prosthesis: An artificial device that replaces a missing body part. *(Ch. 33)*

prothrombin complex concentrate (PCC): a concentrate of vitamin K–dependent clotting factors used to reverse warfarin and, in Canadian practice, for major bleeding on factor Xa inhibitors. *(Ch. 19)*

proto-oncogene: a normal gene that promotes cell growth and division and can become a cancer-driving oncogene when mutated. *(Ch. 9)*

proton pump inhibitor (PPI): a drug that blocks the final step of acid production in the stomach. *(Ch. 24)*

provoked seizure: A seizure caused by a temporary problem, such as a concussion, a fever or alcohol withdrawal, acting on an otherwise normal brain. *(Ch. 30)*

pruritus: Itching; in liver disease, often caused by cholestasis. *(Ch. 26)*

pseudo-relapse: A short-lived return or worsening of earlier MS symptoms caused by heat, fever, infection or fatigue, without new inflammation. *(Ch. 32)*

pseudohyperkalemia: A falsely high potassium result caused by release of potassium from blood cells after the sample is drawn. *(Ch. 3)*

ptosis: Drooping of the upper eyelid. *(Ch. 32)*

pulmonary embolism (PE): Blockage of the pulmonary artery or one of its branches, usually by a clot from a deep vein thrombosis. *(Ch. 15)*

pulmonary embolism rule-out criteria (PERC): Eight clinical checks used for patients already judged at low risk; a patient who meets all eight needs no further testing for pulmonary embolism. *(Ch. 15)*

pulmonary rehabilitation: A supervised, tailored program of exercise training, education and behaviour change for people with chronic lung disease. *(Ch. 14)*

pulse deficit: The apical rate minus the radial rate, counted at the same time by two nurses; a sign that some beats do not reach the periphery. *(Ch. 16)*

pulse oximetry: a non-invasive method that estimates arterial oxygen saturation (SpO2) from the absorption of red and infrared light by pulsing arterial blood. *(Ch. 12)*

pulse pressure: the difference between the systolic and diastolic blood pressures. *(Ch. 6)*

pulseless electrical activity (PEA): An organized rhythm on the monitor without a palpable pulse; a non-shockable arrest rhythm. *(Ch. 16)*

pulsus paradoxus: An exaggerated fall in systolic blood pressure during inspiration; when an effusion is present, a fall of more than 10 mm Hg suggests tamponade. *(Ch. 18)*

punctal occlusion: Pressing on the inner corner of the eye after instilling a drop to reduce the amount of drug that reaches the bloodstream. *(Ch. 36)*

pupillary response: The size, shape and reaction to light of the pupils; a new unequal or sluggish pupil is an urgent cue. *(Ch. 30)*

purpura: patches of bleeding under the skin that are larger than petechiae. *(Ch. 20)*

pyelonephritis: Infection that has reached the kidney, usually with fever, rigors and flank pain or costovertebral angle tenderness. *(Ch. 28)*

pyuria: White blood cells in the urine; it occurs with both infection and asymptomatic bacteriuria. *(Ch. 28)*

QRS complex: The ECG complex produced by ventricular depolarization; normally under 0.12 seconds wide. *(Ch. 16)*

QT interval: The time from the start of the QRS complex to the end of the T wave; corrected for heart rate as the QTc. *(Ch. 16)*

quick SOFA (qSOFA): a three-item bedside score (respiratory rate 22 or more, altered mentation, systolic blood pressure 100 mm Hg or less); not recommended as a single screening tool. *(Ch. 4)*

race: A social category that sorts people by features such as skin colour, name or origin and ranks them unequally; it is not a biological measure. *(Ch. 2)*

race-free equations: Equations for estimated glomerular filtration rate (eGFR) that do not use race, such as the 2021 CKD-EPI equations. *(Ch. 2)*

racialization: The process by which a society treats races as real and distinct and ranks them unequally, with effects on people's economic, political and social lives. *(Ch. 2)*

racialized: Describes a person or group that society treats as belonging to a race and treats unequally because of it; preferred over older terms such as "visible minority." *(Ch. 2)*

radial access: Entry to the arterial system through the radial artery at the wrist for catheterization or PCI. *(Ch. 17)*

radial artery occlusion: Blockage of the radial artery after radial access, a common complication that patent hemostasis helps prevent. *(Ch. 17)*

radical prostatectomy: surgical removal of the whole prostate and some nearby tissue, including the seminal vesicles. *(Ch. 28)*

radioactive iodine therapy (RAI): An oral dose of radioactive iodine that destroys overactive thyroid tissue. *(Ch. 23)*

radon: A colourless, odourless radioactive gas from the breakdown of uranium in soil and rock; the second leading cause of lung cancer in Canada. *(Ch. 13)*

rapid response team: A team with critical care skills that assesses and treats deteriorating patients on general units before cardiac arrest; in Ontario, often called a Critical Care Response Team (CCRT). *(Ch. 6)*

rapid ventricular response (RVR): A ventricular rate above 100 per minute in atrial fibrillation or flutter. *(Ch. 16)*

rate control: An AF treatment strategy that slows the ventricular rate, usually with beta-blockers, nondihydropyridine calcium channel blockers or digoxin. *(Ch. 16)*

Raynaud phenomenon: Episodes in which small arteries of the fingers or toes spasm in cold or stress, so that the skin changes colour and may feel numb or painful. *(Ch. 34)*

re-expansion pulmonary edema: A rare, potentially fatal fluid build-up in a lung that re-expands quickly after removal of pleural fluid or air. *(Ch. 13)*

reasonably foreseeable natural death: The test that decides which set of MAID safeguards applies; it is no longer an eligibility criterion. *(Ch. 10)*

receptive aphasia: Aphasia in which the person has trouble understanding spoken or written language. *(Ch. 31)*

reciprocal changes: ST depression in leads facing the wall opposite an area of ST elevation, supporting acute coronary occlusion. *(Ch. 17)*

recurrent laryngeal nerve: A nerve running close behind the thyroid that controls the vocal cords; injury can cause hoarseness. *(Ch. 23)*

recurrent toxicity: the return of sedation and slow breathing after naloxone wears off, because most opioids act longer than naloxone. *(Ch. 11)*

red blood cell concentrate: a unit of donated red cells with most plasma and white cells removed. *(Ch. 20)*

reduction: The return of broken bone ends to their normal position, either by hand without an incision (closed) or in surgery (open). *(Ch. 33)*

refeeding syndrome: A fall of 10% or more in serum phosphate, potassium or magnesium, with or without organ dysfunction, within 5 days of starting or increasing nutrition after starvation or malnutrition. *(Ch. 3)*

referred pain: pain felt in a body region away from the site of the harmful stimulus, such as pain from an internal organ felt elsewhere *(Ch. 5)*

refractory (irreversible) shock: Shock that persists despite fluids and vasopressors, with cell and organ damage that may be permanent. *(Ch. 6)*

registered psychiatric nurse: A separately regulated nursing profession, found in the western provinces, Yukon and several other jurisdictions, that also uses the letters RPN. *(Ch. 1)*

regurgitation: Backward leakage of blood through a valve that does not close fully. *(Ch. 18)*

rehabilitation: Coordinated, goal-directed care that helps a person regain function and take part in daily life after illness or injury. *(Ch. 31)*

rejection: an immune attack on a transplanted organ; acute rejection is most common in the first year and may cause no symptoms. *(Ch. 27)*

relapse: In MS, new symptoms or a clear worsening of existing ones lasting at least 24 to 48 hours when no outside factor such as infection or heat explains it. *(Ch. 32)*

reliever: An inhaled medicine that opens narrowed airways within minutes and is used for symptoms. *(Ch. 14)*

remodelling: Changes in the size, shape and function of the heart caused by neurohormonal activation, cell loss and scarring. *(Ch. 18)*

renal colic: severe, often wave-like pain in the back, side, lower abdomen or groin caused by a stone moving through or blocking the ureter. *(Ch. 28)*

renin–angiotensin–aldosterone system (RAAS): A hormone system, started by renin from the kidney, that raises blood pressure and keeps sodium and water. *(Ch. 3)*

reperfusion: restoring blood flow through a blocked coronary artery by primary PCI or fibrinolysis. *(Ch. 17)*

repolarization: The return of heart muscle cells to their resting electrical state after depolarization. *(Ch. 16)*

Required Organizational Practices (ROPs): Standardized patient safety practices that organizations accredited by Accreditation Canada must have in place. *(Ch. 1)*

residential schools: Church-run, government-funded schools that removed at least 150,000 First Nations, Inuit and Métis children from their families to assimilate them; the last federally supported schools closed in the late 1990s. *(Ch. 2)*

residual limb: The part of a limb that remains after amputation. *(Ch. 33)*

respiratory acidosis: An acid–base disorder with a low pH caused by a primary rise in $PaCO_2$ from inadequate breathing. *(Ch. 3)*

respiratory alkalosis: An acid–base disorder with a high pH caused by a primary fall in $PaCO_2$ from excessive breathing. *(Ch. 3)*

respiratory fluoroquinolone: a fluoroquinolone antibiotic, such as levofloxacin or moxifloxacin, that is active against the common bacterial causes of pneumonia. *(Ch. 13)*

respiratory secretions: Saliva and secretions that pool in the upper airway near death, causing noisy breathing (the "death rattle") when the person can no longer swallow or cough effectively. *(Ch. 10)*

respiratory syncytial virus (RSV): a common respiratory virus that can cause severe lower respiratory tract disease in older adults and people with chronic conditions. *(Ch. 13)*

responsive behaviours: actions, words and gestures through which a person living with dementia or another neurological, mental health or substance use condition reacts to something that matters to them in their surroundings, often communicating an unmet need. *(Ch. 8)*

resting tremor: Rhythmic shaking, often of one hand, that is present when the limb is at rest. *(Ch. 32)*

restraint: Anything that restricts a person's movement or behaviour in a way the person cannot easily undo, whether physical, environmental or chemical. *(Ch. 8)*

restrictive lung disease: Lung disease in which stiff lungs or a limited chest wall keep the lungs from filling, so lung volumes are small. *(Ch. 14)*

reticulocyte: a young red blood cell recently released from the marrow; the count shows whether the marrow is responding to anemia *(Ch. 20)*

retina: The light-sensitive layer at the back of the eye, whose photoreceptor cells turn light into electrical signals. *(Ch. 36)*

retinal detachment: Separation of the retina from the back of the eye, signalled by sudden flashes, new floaters and a spreading shadow over vision. *(Ch. 36)*

retrograde ejaculation: flow of semen backward into the bladder rather than out through the urethra, common after TURP. *(Ch. 28)*

retroperitoneal bleeding: Bleeding into the space behind the abdominal organs, a hidden complication of femoral access shown by back or flank pain, rising heart rate and falling blood pressure. *(Ch. 17)*

reversibility: A meaningful improvement in airflow after a bronchodilator or a course of controller treatment; in the CTS asthma guideline, an FEV1 rise of at least 12% and 200 mL. *(Ch. 14)*

revised Atlanta classification: An international system that defines acute pancreatitis and grades it as mild, moderately severe or severe according to organ failure and complications. *(Ch. 26)*

rheumatic heart disease: Lasting heart valve damage after acute rheumatic fever, an immune reaction to group A streptococcal throat infection. *(Ch. 18)*

rheumatoid arthritis (RA): A chronic autoimmune disease that inflames the joint lining, usually in the same joints on both sides of the body, and can affect other organs. *(Ch. 34)*

rheumatoid factor (RF): An antibody often present in rheumatoid arthritis; it also appears in some other conditions and is absent in some people with RA. *(Ch. 34)*

rhonchi: low-pitched, continuous, snoring sounds; used interchangeably with "low-pitched wheeze." *(Ch. 12)*

rhythm control: An AF treatment strategy that restores and maintains sinus rhythm with cardioversion, antiarrhythmic drugs or catheter ablation. *(Ch. 16)*

Richmond Agitation–Sedation Scale: A 10-level scale from +4 (combative) to −5 (unarousable), with 0 meaning alert and calm, used to measure sedation and agitation. *(Ch. 15)*

right ventricular infarction: MI involving the right ventricle, often with inferior STEMI; nitroglycerin is used with great caution or avoided. *(Ch. 17)*

right-sided heart failure: Failure of the right ventricle, raising pressure in the systemic veins and causing edema, a raised JVP and organ congestion. *(Ch. 18)*

rigidity: Stiffness of the muscles felt when another person moves the limb. *(Ch. 32)*

routine practices: The infection prevention and control practices used with every patient during all care, including risk assessment, hand hygiene, personal protective equipment, environmental controls and administrative controls. *(Ch. 1)*

Roux-en-Y gastric bypass: bariatric surgery that creates a small stomach pouch joined to the small intestine, bypassing the rest of the stomach. *(Ch. 24)*

rule of nines: A method of estimating the burned body surface in adults that divides the body into areas of 9% or multiples of 9%. *(Ch. 35)*

S3: An extra heart sound in early diastole, just after S2, from rapid ventricular filling. *(Ch. 16)*

S4: An extra heart sound in late diastole, just before S1; always abnormal. *(Ch. 16)*

safe patient handling: An organized approach that uses assessment, equipment, policy and training to move patients without manual lifting where possible. *(Ch. 33)*

same-day admission: Arrival from home on the morning of surgery, with admission to a surgical unit afterwards. *(Ch. 7)*

SBAR: A structured communication tool: Situation, Background, Assessment, Recommendation. *(Ch. 6)*

scope of practice: The range of activities a nurse is permitted and able to perform safely, shaped by authority, competence and context. *(Ch. 1)*

screening: testing people without symptoms to find cancer or precancerous changes early. *(Ch. 9)*

screening mammogram: An X-ray of the breasts in a person with no symptoms, taken to find breast cancer early. *(Ch. 29)*

secondary brain injury: Further brain damage in the hours and days after injury from low oxygen, poor blood flow, swelling and harmful chemical changes. *(Ch. 32)*

secondary fracture prevention: Care that aims to prevent another fracture after a fragility fracture by finding and treating osteoporosis and reducing falls. *(Ch. 33)*

secondary hypertension: Hypertension caused by an identifiable condition or drug. *(Ch. 19)*

secondary intention: Healing of an open wound that fills with granulation tissue from the base up. *(Ch. 35)*

secondary prevention: Care that lowers the risk of another event in a person who already has coronary disease. *(Ch. 17)*

secondary spontaneous pneumothorax: A pneumothorax in a person with established lung disease, or, under BTS guidance, a person over 50 with a smoking history. *(Ch. 15)*

sedation scale: a structured tool for rating how drowsy a patient is, such as the Pasero Opioid-induced Sedation Scale outside critical care or the Richmond Agitation-Sedation Scale in intensive care. *(Ch. 5)*

seizure: A short-lived event of signs or symptoms caused by abnormal, excessive or synchronized electrical activity of neurons in the brain. *(Ch. 30)*

seizure precautions: Safety measures set by employer policy for patients at risk of seizures. *(Ch. 30)*

self-administered MAID: The form of MAID in which the person takes a substance prescribed or provided by a physician or NP. *(Ch. 10)*

self-care: In heart failure, the daily activities of keeping the condition stable, watching for change and responding to it. *(Ch. 18)*

self-management: The day-to-day skills a person uses to live with a chronic condition, such as taking medicines, pacing activity, solving problems and knowing when to seek help. *(Ch. 34)*

self-regulated profession: A profession that the government allows to govern its own members, on condition that it acts in the public interest; in Ontario, nursing is regulated through the College of Nurses of Ontario. *(Ch. 1)*

sensorineural hearing loss: Hearing loss caused by damage to the cochlea or the hearing nerve; usually permanent. *(Ch. 36)*

sentinel lymph node biopsy: Removal of the first lymph node or nodes that drain a tumour, to check whether cancer has spread to them. *(Ch. 29)*

sepsis: Organ dysfunction that threatens life, caused by the body's dysregulated response to an infection. *(Ch. 4)*

septic arthritis: Infection inside a joint; a single hot, swollen, painful joint is treated as septic arthritis until proven otherwise. *(Ch. 34)*

septic shock: a subset of sepsis with severe circulatory, cellular and metabolic changes; clinically, a vasopressor is needed to keep MAP at 65 mm Hg or higher and lactate is above 2 mmol/L despite adequate fluids. *(Ch. 4)*

Sequential Organ Failure Assessment (SOFA) score: a score that grades dysfunction in six organ systems; a rise of 2 or more points with infection defines sepsis. *(Ch. 4)*

serious illness conversation: A structured discussion with a seriously ill person about understanding, prognosis, goals, fears, sources of strength and acceptable trade-offs, used to guide future care. *(Ch. 10)*

seroma: A collection of fluid under the skin after surgery, such as under the skin flap after mastectomy. *(Ch. 29)*

severe asthma: Asthma that stays uncontrolled despite high-level inhaled treatment, needing specialist assessment. *(Ch. 14)*

sexual health history: A focused set of questions about a person's sexual activity, partners, protection, past sexually transmitted and blood-borne infections, symptoms and reproductive health. *(Ch. 29)*

sexually transmitted and blood-borne infection: An infection spread through sexual contact, blood or both. *(Ch. 29)*

SGLT2 inhibitor: a drug that lowers glucose by making the kidneys excrete it, and protects the heart and kidneys *(Ch. 22)*

shear: The force created when deeper tissue slides in one direction while the skin is held in place by a surface, distorting tissue and blood vessels. *(Ch. 35)*

shock: A life-threatening failure of the circulation in which cells cannot get or use enough oxygen. *(Ch. 6)*

shock wave lithotripsy (SWL): use of shock waves from outside the body to break a stone into fragments that pass in the urine. *(Ch. 28)*

short-acting beta2-agonist (SABA): A reliever, such as salbutamol, that relaxes airway smooth muscle within minutes. *(Ch. 14)*

short-acting muscarinic antagonist (SAMA): A short-acting bronchodilator, such as ipratropium, that blocks the nerve signals that tighten airway muscle. *(Ch. 14)*

shunt: blood flow past alveoli that receive no air, so the blood returns to the heart without gaining oxygen. *(Ch. 12)*

sick-day medication guidance: advice on which medications to pause for a short time when a person with diabetes is ill and cannot keep up fluids. *(Ch. 22)*

sick-day rules: instructions for people who take glucocorticoids to increase the dose during illness and to use an emergency injection when tablets cannot be taken. *(Ch. 23)*

sickle cell disease: inherited disorders in which hemoglobin S makes red cells rigid and sickle-shaped, causing hemolysis and blocked blood vessels *(Ch. 20)*

sickle cell trait: carrying one hemoglobin S gene; carriers generally do not have the disease but can pass the gene on *(Ch. 20)*

sighted guide: A technique for walking with a person who is blind or partially sighted, in which the person holds the guide's arm just above the elbow and walks about half a step behind. *(Ch. 36)*

silent aspiration: Aspiration that occurs without coughing or other obvious signs. *(Ch. 24)*

silent chest: A life-threatening sign in asthma in which so little air moves that wheeze can no longer be heard. *(Ch. 14)*

single-pill combination: A tablet that contains two or more blood-pressure-lowering drugs. *(Ch. 19)*

sinoatrial (SA) node: The heart's normal pacemaker, in the high right atrium; its cells fire faster than any others. *(Ch. 16)*

sinus bradycardia: A sinus rhythm slower than normal; the 2018 ACC/AHA/HRS guideline defines it as a sinus rate below 50 per minute. *(Ch. 16)*

sinus tachycardia: A sinus rhythm faster than 100 per minute, usually a response to another problem such as fever, pain or low blood volume. *(Ch. 16)*

site marking: Marking the operative site on the patient's skin before surgery, as policy requires, to prevent wrong-site surgery. *(Ch. 7)*

Sixties Scoop: The removal of many Indigenous children from their families by child welfare authorities, from about the 1960s to the 1980s, and their placement in non-Indigenous foster and adoptive homes. *(Ch. 2)*

Sjögren disease: A systemic autoimmune disease marked by dry eyes and dry mouth, with fatigue, pain and sometimes involvement of other organs. *(Ch. 34)*

skin graft: Healthy skin moved from one part of the body (the donor site) to cover a wound. *(Ch. 35)*

skin tear: A traumatic wound caused by mechanical force, such as handling or adhesive removal, that does not go through the subcutaneous layer; classified as ISTAP Type 1, 2 or 3. *(Ch. 35)*

sleeve gastrectomy: bariatric surgery that removes a large part of the stomach, leaving a narrow tube. *(Ch. 24)*

sliding-scale insulin: a correction-only approach that gives insulin only after glucose is already high; discouraged as the sole treatment in hospital. *(Ch. 22)*

slough: Soft, moist dead tissue in a wound that may be yellow, tan or grey. *(Ch. 35)*

small cell lung cancer (SCLC): A fast-growing lung cancer, about 15% of cases, that has usually spread by the time it is diagnosed. *(Ch. 13)*

snooping: Accessing a person's health information without a professional reason; a privacy breach whatever the motive. *(Ch. 1)*

social determinants of health: The everyday conditions in which people live and work, such as income, education, work, housing, social support and freedom from discrimination and violence. *(Ch. 2)*

sodium–glucose cotransporter 2 (SGLT2) inhibitor: A drug that makes the kidneys excrete glucose and sodium; reduces heart failure hospitalization across ejection fraction categories. *(Ch. 18)*

soft mist inhaler: A device that releases a slow-moving mist of liquid medicine during a slow, deep breath. *(Ch. 14)*

somatic pain: nociceptive pain arising in skin, muscle, bone or joints, often well localized *(Ch. 5)*

spacer: A tube, often with a valve (valved holding chamber), that attaches to a pMDI and holds the puff so it can be breathed in without precise timing. *(Ch. 14)*

spasticity: Increased muscle tone with involuntary spasms and overactive reflexes after damage to the brain or spinal cord. *(Ch. 32)*

speaking valve: A one-way valve on a tracheostomy tube that lets air in and directs exhaled air up through the larynx for speech; used only with the cuff deflated. *(Ch. 12)*

specialist palliative care: Care given by interprofessional teams with advanced palliative training, usually for patients with complex needs. *(Ch. 10)*

speech-language pathologist (SLP): A regulated health professional who assesses swallowing and recommends food textures, drink thickness and swallowing strategies. *(Ch. 24)*

spider angioma: A small red spot with fine vessels radiating outward that fades when the centre is pressed; seen in advanced liver disease. *(Ch. 26)*

spinal anesthesia: a single injection of local anesthetic into the cerebrospinal fluid that numbs and weakens the lower body. *(Ch. 7)*

spinal cord injury (SCI): Damage to the spinal cord that interrupts messages between the brain and the body below the injury. *(Ch. 32)*

spinal fusion: Surgery that joins two or more vertebrae with a bone graft, often held with screws and rods, so that they heal as one bone. *(Ch. 33)*

spinal motion restriction: Keeping the spine as still as possible, for example with a cervical collar and careful movement, when a spine injury is possible. *(Ch. 32)*

spinal shock: A temporary state, beginning immediately after a spinal cord injury, in which spinal reflexes are lost below the injury. *(Ch. 32)*

spirometry: A breathing test that measures how much air a person can blow out after a full breath in, and how fast. *(Ch. 14)*

splinting: Pressing a pillow or hands over an incision to reduce pain during coughing or movement. *(Ch. 7)*

spontaneous awakening trial: A planned daily pause in sedation to let the patient wake. *(Ch. 15)*

spontaneous bacterial peritonitis (SBP): Infection of ascitic fluid without an obvious source, diagnosed by a fluid neutrophil count above 250/mm³. *(Ch. 26)*

spontaneous breathing trial: A daily test in which the ventilated patient breathes with little or no ventilator support to judge readiness for extubation. *(Ch. 15)*

spore: a dormant, hardy form of a bacterium that survives for months on surfaces and resists many disinfectants; hand washing with soap and water is preferred because it physically removes spores. *(Ch. 4)*

squamous cell carcinoma: A skin cancer that starts in the flat squamous cells of the outer epidermis. *(Ch. 35)*

stable angina: predictable chest discomfort brought on by exertion or emotional stress and eased by rest or nitroglycerin, caused by a fixed coronary narrowing. *(Ch. 17)*

stage: a description of the size and extent of a cancer in the body, including spread to lymph nodes or distant sites. *(Ch. 9)*

standard induction: starting buprenorphine after other opioids have been stopped and withdrawal is clearly present. *(Ch. 11)*

stapedectomy: Surgery that replaces a stapes bone that cannot move with a tiny piston to improve hearing. *(Ch. 36)*

Starling forces: The hydrostatic and oncotic pressures that govern fluid movement between plasma and the interstitial space. *(Ch. 3)*

statin: a lipid-lowering drug that is the first-line treatment for people with ASCVD or another statin-indicated condition. *(Ch. 17)*

status epilepticus: A seizure that lasts too long, or repeated seizures without recovery between them; for a convulsive seizure, treatment starts at 5 minutes. *(Ch. 30)*

steatorrhea: Bulky, greasy, foul-smelling stools caused by undigested fat. *(Ch. 26)*

steatotic liver disease: The umbrella term for fat build-up in the liver from any cause. *(Ch. 26)*

stem cell transplant: replacement of blood-forming stem cells with the patient's own (autologous) or a donor's (allogeneic) stem cells. *(Ch. 20)*

STEMI (ST-elevation myocardial infarction): an MI with new ST elevation in at least two contiguous leads, usually from acute occlusion of a coronary artery. *(Ch. 17)*

stenosis: Narrowing and stiffening of a valve opening that obstructs forward blood flow. *(Ch. 18)*

stent: A small mesh tube left in a coronary artery to hold it open after PCI. *(Ch. 17)*

stent thrombosis: A clot that forms inside a stent and suddenly blocks the artery; it presents like a new MI. *(Ch. 17)*

sternal precautions: Limits on arm and upper-body movement that protect the breastbone while it heals after sternotomy. *(Ch. 17)*

steroid emergency card: a card carried by a person who depends on glucocorticoids, telling health care providers how to recognize and treat adrenal crisis. *(Ch. 23)*

Stevens-Johnson syndrome: a severe, usually drug-induced reaction in which the epidermis dies and separates over less than 10% of the body surface, with mucosal ulcers. *(Ch. 21)*

stigma: negative attitudes, beliefs and behaviours directed at a group because of their situation, expressed as stereotypes, prejudice and discrimination at self, social and structural levels. *(Ch. 11)*

stimulant toxicity: an exaggerated sympathetic response to a stimulant, with agitation, fast heart rate, high blood pressure, high body temperature and possible seizures or psychosis. *(Ch. 11)*

stoma: the end of bowel brought through the abdominal wall and folded back at the skin; healthy stomas are moist and pink to red. *(Ch. 25)*

stoma site marking: choosing and marking the best location for a planned stoma before surgery, with the person sitting, standing and bending. *(Ch. 25)*

STOP-Bang: An eight-item yes-or-no screening questionnaire for obstructive sleep apnea. *(Ch. 7)*

STOPP/START: European criteria that flag drugs that may harm older adults (STOPP) and helpful drugs that may have been missed (START); version 3 was published in 2023. *(Ch. 8)*

strangulation: loss of blood supply to a trapped segment of bowel, leading to ischemia, necrosis and perforation; a surgical emergency. *(Ch. 25)*

stress incontinence: Leakage of urine with coughing, sneezing, laughing, lifting or other exertion. *(Ch. 28)*

striae: stretch marks; in Cushing syndrome they may be wide, appearing red to purple on lighter skin and often brown to black on darker skin. *(Ch. 23)*

stridor: a loud, high-pitched, musical sound, mainly on breathing in, that signals a narrowed upper airway and is an emergency. *(Ch. 12)*

stroke: A sudden loss of brain, spinal cord or retinal function caused by a blocked or bleeding blood vessel, with evidence of injury on imaging. *(Ch. 31)*

stroke mimic: A condition, such as low blood glucose, seizure or migraine, that causes sudden stroke-like signs but is not a stroke. *(Ch. 31)*

stroke unit: A hospital unit in one fixed location, set aside for people with stroke, where a stroke-trained interprofessional team provides care. *(Ch. 31)*

stroke volume: the volume of blood the ventricle ejects with each beat. *(Ch. 6)*

structural determinants of health: The large systems, laws, policies and institutional practices, such as governments, labour markets and health, education, immigration and financial systems, that shape how resources and opportunities are distributed and so shape the social determinants. *(Ch. 2)*

subarachnoid hemorrhage (SAH): Bleeding into the space between the brain and its thin covering membranes, often from a ruptured aneurysm. *(Ch. 31)*

subclinical hypothyroidism: A TSH above the reference range with a normal free T4. *(Ch. 23)*

subcutaneous emphysema: air trapped under the skin, felt as crackling under the fingertips. *(Ch. 12)*

subdural hematoma: A collection of blood between the dura and the surface of the brain; it may be acute or chronic. *(Ch. 32)*

Subjective Global Assessment (SGA): A structured bedside assessment that classifies nutrition status using weight change, intake, symptoms, function and physical signs of muscle and fat loss. *(Ch. 24)*

substance use disorder: a health condition in which a person keeps using a substance despite significant problems linked to that use, diagnosed when at least 2 of 11 criteria occur within 12 months and graded mild, moderate or severe. *(Ch. 11)*

substitute decision-maker (SDM): The person who makes a treatment decision for a patient who is incapable for that decision, chosen according to the ranked list in Ontario's Health Care Consent Act, 1996. *(Ch. 1)*

substitute decision-making: An approach in which another person makes a decision on behalf of a person who is incapable of making it. *(Ch. 2)*

sudden sensorineural hearing loss (SSNHL): A rapid sensorineural hearing loss developing over up to 72 hours, commonly defined as a loss of 30 dB or more across three neighbouring pitches; an urgent problem. *(Ch. 36)*

superficial burn: A burn involving only the epidermis; the skin is intact, painful and without blisters. *(Ch. 35)*

superficial vein thrombosis (SVT): a clot with inflammation in a vein near the skin surface. *(Ch. 19)*

superior vena cava syndrome: Swelling of the face, neck and arms with shortness of breath caused by narrowing of the superior vena cava by a tumour or clot. *(Ch. 9)*

supervised consumption site: a service where people use drugs they bring with them in the presence of trained staff who can respond to an overdose; it operates under a federal exemption. *(Ch. 11)*

support surface: A mattress, overlay or cushion designed to redistribute pressure; it does not replace repositioning. *(Ch. 35)*

supported decision-making: An approach in which trusted people help a person understand choices and express a decision, while the decision remains the person's own. *(Ch. 2)*

supraventricular tachycardia (SVT): A regular, narrow-complex tachycardia that starts above the ventricles, often from a loop involving the AV node. *(Ch. 16)*

surgical aortic valve replacement (SAVR): Open-heart surgery to replace the aortic valve. *(Ch. 18)*

surgical menopause: Menopause that begins abruptly when both ovaries are removed before natural menopause. *(Ch. 29)*

Surgical Safety Checklist: A structured set of checks completed aloud by the whole surgical team at three set points during each operation. *(Ch. 7)*

surgical site infection: An infection of a surgical incision or of the deeper tissues or organ space after an operation. *(Ch. 35)*

survivorship care plan: A written summary of a person's cancer diagnosis and treatment with a plan for follow-up, signs to report, late effects and wellness. *(Ch. 9)*

sustained virologic response: No hepatitis C virus found in the blood 12 weeks after treatment ends; considered a cure. *(Ch. 26)*

swallowing screen: A brief pass-or-fail check, done by a trained team member with a validated protocol, that identifies people who need a full swallowing assessment. *(Ch. 24)*

symptom-triggered treatment: giving withdrawal medication when a patient's withdrawal score reaches a set threshold, rather than on a fixed schedule. *(Ch. 11)*

symptomatic intracranial hemorrhage: Bleeding in the brain that worsens the person's condition, the most serious complication of thrombolysis. *(Ch. 31)*

synchronized cardioversion: A shock timed to the QRS complex, used for tachycardias with a pulse. *(Ch. 16)*

syndrome of inappropriate antidiuretic hormone secretion (SIADH): Continued ADH action despite dilute plasma, causing water retention and hyponatremia in a patient with normal volume status. *(Ch. 3)*

synovial joint: A freely movable joint in which cartilage-covered bone ends sit inside a capsule lined with synovium and filled with synovial fluid. *(Ch. 34)*

synovitis: Inflammation of the synovium, the lining of a synovial joint. *(Ch. 34)*

synovium: The inner lining of a joint capsule, which makes the fluid that lubricates the joint and nourishes the cartilage. *(Ch. 34)*

syphilis: A sexually transmitted infection caused by Treponema pallidum that progresses through primary, secondary, latent and tertiary stages. *(Ch. 29)*

systemic inflammatory response syndrome (SIRS): a set of criteria (temperature, heart rate, respiratory rate, white cell count) once used to define sepsis; no longer part of the definition. *(Ch. 4)*

systemic lupus erythematosus: A chronic autoimmune disease in which antibodies against the body's own cell parts cause inflammation in many organs. *(Ch. 34)*

systemic sclerosis: A rare autoimmune disease that damages small blood vessels and causes thickening and scarring of the skin and internal organs. *(Ch. 34)*

systemic vascular resistance: the resistance to blood flow created by the tone of the small arteries. *(Ch. 6)*

systolic dysfunction: Weak contraction of the ventricle, so a smaller share of its blood is ejected with each beat. *(Ch. 18)*

tactile fremitus: the vibration felt through the chest wall when a patient speaks. *(Ch. 12)*

takotsubo cardiomyopathy: Sudden, temporary weakness of the left ventricle, usually triggered by emotional or physical stress, that can mimic a myocardial infarction; also called stress cardiomyopathy. *(Ch. 18)*

target-organ damage: Injury to the brain, eyes, heart, kidneys or large arteries caused by high blood pressure. *(Ch. 19)*

targeted interventions: Fall prevention measures matched to a person's own risk factors, such as scheduled toileting, supervised mobility or medication review. *(Ch. 8)*

targeted therapy: treatment that acts on specific proteins that drive the growth and spread of cancer cells. *(Ch. 9)*

TB disease: Active illness from M. tuberculosis multiplying in the body; TB disease in the lungs or larynx can spread to others. *(Ch. 13)*

TB infection: A state in which M. tuberculosis is alive but held in check by the immune system; the person has no symptoms and cannot spread TB (formerly called latent TB infection). *(Ch. 13)*

teach-back: A technique in which the patient or caregiver explains or shows, in their own words, what they have been taught; it checks how clearly the nurse taught. *(Ch. 1)*

telemetry: Continuous ECG monitoring that sends the signal from a wireless transmitter to a central station. *(Ch. 16)*

telestroke: A video assessment by a stroke physician at another centre to support treatment and transfer decisions. *(Ch. 31)*

tenesmus: A painful feeling of needing to pass stool even when the rectum is empty. *(Ch. 25)*

tension pneumothorax: air trapped in the pleural space under rising pressure, which collapses the lung and impairs blood return to the heart. *(Ch. 6)*

terminal delirium: Delirium in the last days of life that is part of the dying process and usually not reversible; care focuses on comfort and safety. *(Ch. 10)*

terminal restlessness: Agitation or delirium in the last days of life that has no reversible cause. *(Ch. 10)*

tetraplegia: Weakness or paralysis of the arms, trunk and legs from an injury to the cervical spinal cord. *(Ch. 32)*

texture-modified diet: A diet that changes food texture, drink thickness or both to make swallowing safer. *(Ch. 24)*

thalassemia: inherited disorders in which too little of one hemoglobin protein chain is made *(Ch. 20)*

third spacing: A shift of fluid out of the circulation into spaces where it cannot support blood pressure, such as the bowel, abdomen or inflamed tissue. *(Ch. 3)*

third-degree AV block: Complete AV block in which no atrial impulses reach the ventricles, so P waves and QRS complexes are unrelated. *(Ch. 16)*

thoracentesis: Removal of fluid from the pleural space with a needle or small catheter, for diagnosis or relief of symptoms. *(Ch. 13)*

three-way catheter: an indwelling urinary catheter with separate channels for the balloon, drainage and irrigation inflow. *(Ch. 28)*

thrill: the vibration felt over a working fistula or graft; normally soft and continuous. *(Ch. 27)*

thrombocytopenia: a platelet count below the laboratory's reference range, from decreased production or from increased destruction, consumption or sequestration of platelets. *(Ch. 20)*

thrombolysis: Treatment with a drug that dissolves a blood clot, such as alteplase. *(Ch. 15)*

thrombophilia: An inherited or acquired tendency for blood to clot more readily than normal. *(Ch. 15)*

thunderclap headache: A severe headache that reaches its peak almost at once; it needs emergency assessment. *(Ch. 30)*

thyroid eye disease: An autoimmune disorder of the tissues around the eyes, closely linked to Graves disease, that causes eyelid retraction, proptosis, swelling and double vision. *(Ch. 23)*

thyroid storm: Life-threatening thyrotoxicosis with failure of one or more organs, usually triggered by another illness. *(Ch. 23)*

thyroid-stimulating hormone (TSH): The pituitary hormone that drives the thyroid to make thyroid hormone; the most reliable single test of thyroid function in most people. *(Ch. 23)*

thyroidectomy: Surgical removal of all (total) or part of the thyroid gland. *(Ch. 23)*

thyrotoxicosis: The state caused by too much thyroid hormone acting on the tissues, whatever the cause. *(Ch. 23)*

tidal volume: The volume of air delivered with each breath. *(Ch. 15)*

tidalling: The rise and fall of fluid in the water seal or tubing with breathing, which shows that a chest drain is open to the pleural space. *(Ch. 15)*

time in range: the percentage of CGM readings between 3.9 and 10.0 mmol/L *(Ch. 22)*

time-out: The checklist phase completed just before the skin incision, in which the team confirms patient, procedure and site aloud. *(Ch. 7)*

tinnitus: The perception of sound, such as ringing, buzzing or hissing, with no outside source. *(Ch. 36)*

TNM: an international staging system describing the primary tumour (T), regional lymph nodes (N) and distant metastasis (M). *(Ch. 9)*

tolerance: the need for more of a drug to produce the same effect after repeated use. *(Ch. 5)*

tonic-clonic seizure: A seizure with a stiffening phase followed by rhythmic jerking of the limbs. *(Ch. 30)*

tonicity: The effect of a fluid on cell volume, determined by solutes that cannot cross cell membranes freely. *(Ch. 3)*

tophus: A firm, chalk-like deposit of urate crystals under the skin, often on the ear, elbow or finger pads (plural tophi). *(Ch. 34)*

total body surface area: The whole skin surface of the body, used as the basis for expressing the extent of a burn as a percentage (TBSA). *(Ch. 35)*

total hip arthroplasty: Surgery that replaces the femoral head and lines the hip socket with artificial parts. *(Ch. 33)*

total knee arthroplasty: Surgery that resurfaces the worn ends of the femur and tibia, and often the kneecap, with artificial parts. *(Ch. 33)*

total pain: Cicely Saunders's concept of suffering with physical, psychological, social, emotional and spiritual parts. *(Ch. 10)*

toxic epidermal necrolysis: the most extensive form of the same reaction as Stevens-Johnson syndrome, with detachment of more than 30% of the body surface. *(Ch. 21)*

toxic megacolon: Marked widening of an inflamed colon, seen on X-ray, with systemic illness and a risk of perforation. *(Ch. 25)*

tracheostomy: A surgical opening into the front of the trachea, held open by a tube. *(Ch. 12)*

Track 1: The MAID pathway for a person whose natural death is reasonably foreseeable. *(Ch. 10)*

Track 2: The MAID pathway for a person whose natural death is not reasonably foreseeable; it adds consultation with an expert when neither assessor has expertise in the condition, discussion of other means of relief and at least 90 clear days from the first assessment to provision. *(Ch. 10)*

track-and-trigger system: A system in which nurses track a patient's early warning score over time and preset scores trigger a defined response, such as more frequent monitoring or urgent review. *(Ch. 6)*

traction: A pulling force applied to a limb, through the skin or through a pin in the bone, to restore and keep a broken bone's alignment and length. *(Ch. 33)*

traditional tobacco: Tobacco used by many First Nations as a sacred medicine in ceremony, offerings and gifts; distinct from commercial tobacco. *(Ch. 14)*

transcatheter aortic valve implantation (TAVI): Placement of a replacement aortic valve through a catheter, usually inserted in the femoral artery. *(Ch. 18)*

transcatheter edge-to-edge repair (TEER): A catheter-delivered clip that joins the mitral valve leaflets to reduce regurgitation. *(Ch. 18)*

transcutaneous pacing: Emergency pacing through adhesive pads on the chest, used as a bridge to transvenous or permanent pacing. *(Ch. 16)*

transduction: the conversion of a harmful stimulus into an electrical signal by nociceptors *(Ch. 5)*

transfusion reaction: any harmful response to a blood component or product. *(Ch. 20)*

transfusion-associated circulatory overload (TACO): fluid overload from transfusion, during or up to 12 hours after it, that causes breathlessness and signs of volume overload such as pulmonary edema. *(Ch. 20)*

transfusion-related acute lung injury (TRALI): sudden lung injury, with fluid in the lungs that is not caused by heart failure, during a transfusion or within 6 hours after it. *(Ch. 20)*

transgender: Describes a person whose gender identity differs from the sex they were assigned at birth. *(Ch. 2)*

transient ischemic attack (TIA): A brief episode of stroke-like symptoms caused by ischemia, with no infarct on imaging; symptoms resolve within 24 hours, usually within an hour. *(Ch. 31)*

transition in care: Any move of a patient between settings or care teams, including admission, transfer and discharge. *(Ch. 1)*

transitions of care: Moves of a patient from one setting or team to another, such as from the stroke unit to rehabilitation or home. *(Ch. 31)*

transmission: the movement of pain signals from the periphery through the spinal cord to the brain *(Ch. 5)*

transsphenoidal surgery: removal of a pituitary tumour through the nose and sphenoid sinus. *(Ch. 23)*

transudate: Low-protein pleural fluid caused by pressure or low blood protein, as in heart failure. *(Ch. 13)*

transurethral resection of bladder tumour (TURBT): removal of a bladder tumour through a scope passed into the bladder, with a sample of the muscle beneath. *(Ch. 28)*

transurethral resection of the prostate (TURP): removal of the inner prostate tissue with an electrical wire loop passed through the urethra. *(Ch. 28)*

transurethral resection syndrome (TUR syndrome): dilutional hyponatremia and fluid overload caused by absorption of irrigating fluid during transurethral surgery. *(Ch. 28)*

trauma- and violence-informed care (TVIC): An approach to care that recognizes the links between violence, trauma and health, including ongoing and structural violence, and focuses on creating safety, choice and control without requiring disclosure. *(Ch. 2)*

traumatic brain injury (TBI): Damage to the brain from an outside force, such as a blow to the head or a jolt that moves the brain quickly inside the skull. *(Ch. 32)*

treat-to-target: An approach that sets a goal such as remission, measures disease activity regularly and adjusts treatment until the goal is reached. *(Ch. 34)*

trichomoniasis: A sexually transmitted infection caused by the parasite Trichomonas vaginalis. *(Ch. 29)*

triple therapy: Maintenance treatment with a LAMA, a LABA and an ICS, usually in one inhaler, for people with COPD at high risk of exacerbations. *(Ch. 14)*

troponin: A blood marker of heart muscle injury; a raised level in pulmonary embolism suggests right ventricular strain. *(Ch. 15)*

Trousseau's sign: Spasm of the hand and wrist within 3 minutes of inflating a blood pressure cuff above systolic pressure; a sign of hypocalcemia. *(Ch. 3)*

true urine output: during bladder irrigation, the total volume drained minus the volume of irrigation instilled. *(Ch. 28)*

tuberculin skin test (TST): A test in which purified protein derivative is injected into the skin and the induration is measured 48 to 72 hours later to detect TB infection. *(Ch. 13)*

tuberculosis (TB): An infection caused by Mycobacterium tuberculosis that spreads through the air and most often affects the lungs. *(Ch. 13)*

tumour lysis syndrome (TLS): Metabolic imbalances (high potassium, phosphate and uric acid, low calcium) and possible kidney injury caused by the rapid breakdown of many cancer cells. *(Ch. 9)*

tumour marker: a substance made by cancer cells, or by the body in response to cancer, that can be measured to help monitor the disease. *(Ch. 9)*

tumour suppressor gene: a gene that normally slows cell division, repairs DNA or triggers apoptosis; loss of its function allows uncontrolled growth. *(Ch. 9)*

tunnelling: A narrow channel extending from a wound into deeper tissue. *(Ch. 35)*

Two-Spirit: An English umbrella term used by some Indigenous people for an identity rooted in their own cultures, which may include gender, spiritual and sexual identity. *(Ch. 2)*

tympanic membrane: The eardrum, the thin membrane at the end of the ear canal that vibrates with sound. *(Ch. 36)*

tympanoplasty: Surgery to repair a hole in the eardrum. *(Ch. 36)*

type 1 diabetes: diabetes caused mainly by destruction of the pancreatic beta cells, usually autoimmune, leading to insulin deficiency and a tendency to ketoacidosis *(Ch. 22)*

type 2 diabetes: diabetes caused by insulin resistance together with a beta-cell defect that leaves insulin output too low *(Ch. 22)*

type 2 myocardial infarction: MI caused by an imbalance between the heart's oxygen supply and demand, such as severe anemia or hypotension, without acute plaque disruption. *(Ch. 17)*

ulcerative colitis (UC): A form of IBD limited to the colon, starting in the rectum and spreading upward without gaps, that inflames the inner lining. *(Ch. 25)*

ultrafiltration: removal of extra water from the blood by pressure during dialysis. *(Ch. 27)*

undermining: Tissue destroyed under intact skin at a wound's edge, forming a shelf. *(Ch. 35)*

undetectable = untransmittable (U=U): the scientific consensus that a person living with HIV who takes treatment and keeps a viral load below 200 copies/mL does not transmit HIV through sex. *(Ch. 21)*

unfractionated heparin (UFH): an anticoagulant given IV or subcutaneously that boosts antithrombin; monitored by aPTT or anti-Xa level. *(Ch. 19)*

United Nations Declaration on the Rights of Indigenous Peoples (UNDRIP): A declaration adopted by the United Nations General Assembly in 2007, which sets minimum standards for Indigenous rights, including the right to traditional medicines and to health services without discrimination (Article 24). *(Ch. 2)*

universal fall precautions: Basic safety measures used for every patient regardless of fall risk, such as a low, locked bed, a call bell within reach, good lighting and non-slip footwear. *(Ch. 8)*

unregulated care provider (UCP): A care provider who is not regulated under the Regulated Health Professions Act, 1991 and has no legally defined scope of practice; in Ontario, most often a personal support worker. *(Ch. 1)*

unregulated drug supply: drugs made and sold outside legal and quality controls, often containing fentanyl and other toxic substances of unknown strength. *(Ch. 11)*

unstable angina: myocardial ischemia at rest or on minimal exertion without heart muscle cell death. *(Ch. 17)*

unstageable pressure injury: A full-thickness pressure injury whose depth cannot be seen because slough or eschar covers the base. *(Ch. 35)*

upper gastrointestinal bleeding (UGIB): bleeding from the esophagus, stomach or duodenum. *(Ch. 24)*

urate-lowering therapy: A long-term medicine, such as allopurinol, that lowers the body's urate level to dissolve crystals and prevent gout flares. *(Ch. 34)*

uremia: the effects of wastes retained when the kidneys fail, such as reduced appetite, nausea, fatigue and itch, and in severe cases bleeding, encephalopathy and pericarditis *(Ch. 27)*

ureteral stent: a thin, flexible tube placed in the ureter, from the kidney to the bladder, to keep urine draining. *(Ch. 28)*

ureteroscopy: passing a thin scope through the urethra and bladder into the ureter to break up or remove a stone. *(Ch. 28)*

urge incontinence: Leakage of urine with or right after a sudden, strong urge to void that is hard to delay; also called urgency incontinence. *(Ch. 28)*

uric acid: A waste product of purine breakdown that the kidneys remove; a high blood level can lead to urate crystal deposits. *(Ch. 34)*

urinary incontinence: Any involuntary leakage of urine. *(Ch. 28)*

urinary retention: Inability to empty the bladder completely or at all; it may be acute or chronic. *(Ch. 28)*

urinary tract infection (UTI): An infection anywhere in the urinary tract, from the urethra to the kidneys. *(Ch. 28)*

urine albumin-to-creatinine ratio (ACR): a random urine test, reported in mg/mmol, that measures albumin in the urine and is used to detect and classify kidney damage *(Ch. 27)*

urine culture: A laboratory test that identifies bacteria in urine, counts them and tests their susceptibility to antibiotics. *(Ch. 28)*

urine specific gravity: A measure of urine concentration compared with water. *(Ch. 3)*

urolithiasis: stones anywhere in the urinary tract. *(Ch. 28)*

urosepsis: Sepsis that starts from an infection of the urinary tract. *(Ch. 28)*

urostomy: a stoma that drains urine into a pouch on the abdomen. *(Ch. 28)*

uterine fibroids: Non-cancerous growths of the muscle of the uterus. *(Ch. 29)*

vaccine hesitancy: a delay in or refusal of vaccination because of concerns about vaccines. *(Ch. 21)*

vagal manoeuvre: An action that increases vagal tone to slow AV node conduction, such as a Valsalva manoeuvre, used first for stable regular narrow-complex tachycardia. *(Ch. 16)*

vaginal estrogen: Low-dose estrogen placed in the vagina to treat genitourinary syndrome of menopause. *(Ch. 29)*

vancomycin-resistant enterococci (VRE): bowel bacteria (enterococci) that no longer respond to vancomycin. *(Ch. 4)*

varenicline: A prescription cessation medication that partly stimulates nicotine receptors, easing cravings and withdrawal. *(Ch. 14)*

vasculitis: Inflammation of the walls of blood vessels. *(Ch. 34)*

vaso-occlusive crisis: an episode of acute pain caused by sickled cells blocking blood flow *(Ch. 20)*

vasomotor symptoms: Hot flashes and night sweats, the most common symptoms of menopause. *(Ch. 29)*

vasopressor: a drug that constricts blood vessels to raise blood pressure. *(Ch. 6)*

vegetation: A mass of clot, bacteria and inflammatory cells attached to a heart valve or other endocardial surface in infective endocarditis. *(Ch. 18)*

venous thromboembolism (VTE): a blood clot in a vein, including deep vein thrombosis and pulmonary embolism. *(Ch. 7)*

ventilation: the movement of air into and out of the lungs. *(Ch. 12)*

ventilation–perfusion (V/Q) mismatch: an imbalance between the air reaching parts of the lung and the blood flowing past them; it causes hypoxemia more often than any other mechanism. *(Ch. 12)*

ventilation–perfusion (V/Q) scan: A nuclear medicine scan that compares where air and blood reach the lungs; preferred when contrast or radiation is a concern. *(Ch. 15)*

ventilator-associated pneumonia: Pneumonia that develops in a patient receiving invasive mechanical ventilation. *(Ch. 15)*

ventilator-associated pneumonia (VAP): pneumonia that develops more than 48 hours after endotracheal intubation. *(Ch. 13)*

ventricular fibrillation (VF): Chaotic electrical activity in the ventricles with no organized QRS complexes and no cardiac output. *(Ch. 16)*

ventricular tachycardia (VT): A fast rhythm from the ventricles with wide QRS complexes that may or may not produce a pulse. *(Ch. 16)*

Venturi mask: An air-entrainment mask that mixes oxygen with room air through a valve to give a fixed oxygen concentration. *(Ch. 12)*

verbal descriptor scale: a self-report scale on which the patient chooses a word, such as mild, moderate or severe, to describe pain intensity *(Ch. 5)*

vertigo: A false sense that the person or the surroundings are moving. *(Ch. 36)*

vesicant: a drug that can blister and destroy tissue if it leaks out of a vein. *(Ch. 9)*

vestibular rehabilitation: Exercises that help the brain adapt to balance problems; offered for ongoing imbalance but not during an acute attack of vertigo. *(Ch. 36)*

video remote interpreting (VRI): Sign language interpretation provided by an interpreter who joins by video on a screen. *(Ch. 36)*

viral load: the amount of HIV RNA in the blood, used to judge whether antiretroviral therapy is working. *(Ch. 21)*

Virchow's triad: The three conditions that promote clotting: stasis of blood, injury to the vessel wall and hypercoagulability. *(Ch. 15)*

visceral pain: nociceptive pain arising in internal organs, often harder to locate than somatic pain *(Ch. 5)*

visual acuity: The sharpness of vision at a set distance, often measured with a letter chart such as the Snellen chart. *(Ch. 36)*

vital capacity: The largest volume of air a person can breathe out after a full breath in; a bedside measure of breathing muscle strength. *(Ch. 32)*

volvulus: a twist of a loop of bowel, most often the sigmoid colon or cecum, on its own mesentery. *(Ch. 25)*

von Willebrand disease (VWD): the most common inherited bleeding disorder, caused by a lack or defect of von Willebrand factor; it often causes nosebleeds, bruising and heavy menstrual bleeding. *(Ch. 20)*

waiver of final consent: A written arrangement, available only in Track 1, that allows MAID to proceed on a set date if the person loses capacity, unless they refuse or resist by words, sounds or gestures; also called Audrey's Amendment. *(Ch. 10)*

water seal: The chamber of a chest drainage unit in which a column of water lets air leave the chest but stops it from flowing back, acting as a one-way valve. *(Ch. 15)*

weaning: The process of reducing ventilator support until the patient breathes without it. *(Ch. 15)*

wearing off: The return of Parkinson symptoms before the next dose of medication is due. *(Ch. 32)*

weight bias: negative attitudes, beliefs or actions toward people because of their body weight. *(Ch. 24)*

weight stigma: The social devaluing of people because of their body size, which can show up as stereotypes, judgmental language and equipment or practices that do not fit them. *(Ch. 2)*

Wells rule: A structured clinical rule that estimates the pretest probability of pulmonary embolism from findings such as signs of DVT, heart rate, recent surgery or immobility, and past VTE. *(Ch. 15)*

Wernicke encephalopathy: an acute, potentially fatal brain disorder caused by thiamine deficiency, classically with confusion, ataxia and abnormal eye movements. *(Ch. 11)*

wet suction: A chest drainage design in which the height of a water column limits the level of suction. *(Ch. 15)*

wheeze: a continuous, musical sound produced by narrowed airways, usually heard when breathing out. *(Ch. 12)*

whispered voice test: A bedside hearing screen in which the examiner, out of the person's sight, whispers a mix of numbers and letters for the person to repeat, testing each ear separately. *(Ch. 36)*

white-coat hypertension: Raised blood pressure in the office with normal readings at home or on ambulatory monitoring. *(Ch. 19)*

window period: the time between HIV infection and the point when a test can reliably detect it; up to 12 weeks. *(Ch. 21)*

withdrawal seizure: a generalized tonic-clonic seizure caused by alcohol withdrawal, usually within the first two days after the last drink. *(Ch. 11)*

work of breathing: the effort the breathing muscles spend to move air; signs of increased work include accessory muscle use, retractions and speaking in short phrases. *(Ch. 12)*

wound bed preparation: A framework for wound care that starts by treating the cause, addressing the person's concerns and deciding whether a wound can heal, then guides local care. *(Ch. 35)*

written action plan: A personal written guide that tells a person with asthma how to recognize worsening, step up treatment and seek help. *(Ch. 14)*

YEARS: A diagnostic approach for suspected pulmonary embolism that combines three clinical items with a D-dimer threshold that depends on whether any item is present. *(Ch. 15)*

BACK MATTER — OPEN EDUCATIONAL RESOURCE ATTRIBUTIONS *Appendix C*

C Complete Figure Credits & Licences (246 Figures)

Figure 1.1 (Ch. 1): A nurse measures a patient's blood pressure at the bedside. Regular, careful assessment underlies every other part of medical-surgical nursing care. (credit: “Blood Pressure Monitoring” by NIH Clinical Center/Flickr, CC BY 2.0)

Figure 1.2 (Ch. 1): A nurse checks an older man's blood pressure in his home. Medical-surgical nursing continues after discharge through home care, telephone follow-up and remote monitoring. (credit: “Telehealth - Older man and nurse using blood pressure” by Tunstall Telehealthcare/Flickr, CC BY 2.0)

Figure 1.3 (Ch. 1): (a) Qikiqtani General Hospital, the territorial hospital in Iqaluit, Nunavut. (b) Tammaativvik, a boarding home in Iqaluit for Inuit patients who travel from other communities for care at the hospital. (credit: (a) “Qikiqtani General Hospital” by OhanaUnited/Wikimedia Commons, CC BY-SA 4.0; (b) “Tammaativvik boarding home” by OhanaUnited/Wikimedia Commons, CC BY-SA 4.0)

Figure 1.4 (Ch. 1): An Ornge helicopter departs St. Michael's Hospital in Toronto. Ornge provides air ambulance service and medical transport in Ontario for people who are critically ill or injured (Ornge, n.d.). (credit: “Ornge Agusta Westland AW 139 C-GYNN” by BriYYZ/Wikimedia Commons, CC BY-SA 2.0)

Figure 1.5 (Ch. 1): A health care assistant helps a patient with fluids. Unregulated care providers, such as PSWs in Ontario, give much of the personal care on medical-surgical units, within the role their employer sets. (credit: “A healthcare assistant pouring water for a patient” by Adrian Wressell, Heart of England NHS FT/Wellcome Collection, CC BY 4.0)

Figure 1.6 (Ch. 1): A nurse records a patient's vital signs, including oxygen saturation from a finger probe. Recognizing cues begins with accurate, regular assessment. (credit: “A nurse carrying out observations on a patient” by Adrian Wressell, Heart of England NHS FT/Wellcome Collection, CC BY 4.0)

Figure 1.7 (Ch. 1): A nurse documents in the electronic health record on a mobile workstation in the patient's room. The patient's face and the screen have been blurred to protect privacy. (credit: modification of “Princess Alexandra Hospital nurse with mobile computer work station” by Kgbo/Wikimedia Commons, CC BY-SA 4.0)

Figure 1.8 (Ch. 1): A nurse prepares medications from a locked medication cart. Each medication is checked against the order and the patient before it is given. (credit: “Nurse during a drug administration on a UK hospital ward” by Adrian Wressell, Heart of England NHS FT/Wellcome Collection, CC BY 4.0)

Figure 1.9 (Ch. 1): A hospital identification band. The nurse confirms at least two person-specific identifiers, such as name and date of birth, before giving a medication or treatment (Health Standards Organization, 2024). Identifying details have been blurred. (credit: modification of “Wrist Identification Band” by Whoisjohngalt/Wikimedia Commons, CC BY-SA 4.0)

Figure 1.10 (Ch. 1): A weekly pill organizer. A best possible medication history asks how the patient actually takes each medication at home, including what goes into an organizer like this one. (credit: “Heptagonal objects A weekly medicine box” by יוח יוסי/Wikimedia Commons, CC BY-SA 4.0)

Figure 1.11 (Ch. 1): An older adult walks with a walking frame and a physiotherapist. Getting up early and often during a hospital stay helps prevent hospitalization-associated disability. (credit: “Female physiotherapist with elderly female patient” by Adrian Wressell, Heart of England NHS FT/Wellcome Collection, CC BY 4.0)

Figure 2.1 (Ch. 2): Braided sweetgrass (Hierochloe odorata), one of the sacred medicines used in First Nations, Inuit and Métis smudging and healing ceremonies. (credit: “Braided Sweet Grass” by Jamfam1000/Wikimedia Commons, CC BY-SA 4.0)

Figure 2.2 (Ch. 2): The health centre in Cambridge Bay, Nunavut. When a patient from a northern or remote community is discharged, the nurse connects with the community's health centre so that care continues at home. (credit: “38 Health centre” by CambridgeBayWeather/Wikimedia Commons, CC BY-SA 4.0)

Figure 2.3 (Ch. 2): A mobile community health and wellness clinic van, one model used to bring primary care, wound care and harm reduction directly to underserved neighbourhoods. (credit: “Mobile health van - 2021-08-27 - Sarah Stierch” by Sarah Stierch [Missvain]/Wikimedia Commons, CC BY 4.0)

Figure 3.1 (Ch. 3): Pitting edema of the lower leg: pressing with a finger leaves dents that fill slowly. (credit: “Oedema, finger marks” by John Campbell/Flickr, public domain)

Figure 3.2 (Ch. 3): An electronic infusion pump delivers IV fluid at a set rate. The nurse checks the fluid, rate and volume on the pump against the order. (credit: “Electronic infusion device (EID)” by Glynda Rees Doyle and Jodie Anita McCutcheon/BCcampus, CC BY 4.0)

Figure 3.3 (Ch. 3): A peripheral IV catheter in the forearm, held in place with a clear dressing so the site can be seen. The nurse looks at the site and the skin around it at every assessment. (credit: “Peripheral intravenous (IV) catheter (PIV)” by Glynda Rees Doyle and Jodie Anita McCutcheon/BCcampus, CC BY 4.0)

Figure 3.4 (Ch. 3): A 12-lead ECG from a patient with a serum potassium of 7.0 mmol/L, showing tall, peaked T waves. (credit: “ECG Hyperkalaemia peaked T waves serum potassium 7.0” by LITFL/Life in the Fast Lane, CC BY-NC-SA 4.0)

Figure 3.5 (Ch. 3): A re-creation of the hand posture of a positive Trousseau's sign: the wrist and knuckles flex, the fingers straighten and the thumb draws in. (credit: “Trousseau's Sign of Latent Tetany” by Tmdswan/Wikimedia Commons, CC BY-SA 4.0)

Figure 3.6 (Ch. 3): (a) Blood samples in syringes: venous blood is darker and arterial blood brighter red. (b) A blood gas analyzer, which measures pH, blood gases and electrolytes in a small sample of blood. (credit: (a) “Venous and arterial blood rotated and cropped” by Wesalius/Wikimedia Commons, CC BY 4.0; (b) “Cobas221A” by J3D3/Wikimedia Commons, CC BY-SA 3.0)

Figure 4.1 (Ch. 4): Cellulitis of the toes and forefoot. Spreading redness and swelling are local signs of inflammation and infection; on darker skin, redness can be harder to see, so the nurse also checks warmth, swelling and pain.

Figure 4.2 (Ch. 4): A blood culture bottle that has turned cloudy because organisms are growing in it. The laboratory then identifies the organism and tests which antimicrobials work against it.

Figure 4.3 (Ch. 4): A wall-mounted alcohol-based hand rub dispenser in a hospital in the United States. (credit: “Purell hand sanitizer device at Memorial Regional Hospital” by Claudia Brauer/Wikimedia Commons, CC BY 2.0)

Figure 4.4 (Ch. 4): (a) *Clostridioides difficile* bacteria from a stool sample, seen with a scanning electron microscope. (b) Methicillin-resistant *Staphylococcus aureus* (MRSA, gold) and a dead human neutrophil (red), with colour added. (credit: (b) “Scanning electron micrograph of Methicillin-resistant Staphylococcus aureus (MRSA) and a dead Human neutrophil” by NIAID/Wikimedia Commons, CC BY 2.0)

Figure 5.1 (Ch. 5): (a) A patient-controlled analgesia (PCA) pump with a morphine cassette for intravenous use. (b) A pump set up for an epidural infusion of fentanyl with bupivacaine; the label reads “Epidural Use Only.” These labels are from the United States; Canadian products are labelled differently. (credit: (a) “PCA-02” and (b) “PCA-01” by DiverDave/Wikimedia Commons, CC BY-SA 3.0)

Figure 5.2 (Ch. 5): A take-home naloxone kit as distributed in British Columbia. (credit: “NaloxoneKit” by James Heilman, MD/Wikimedia Commons, CC BY-SA 4.0)

Figure 6.1 (Ch. 6): (a) A bedside monitor showing heart rate, oxygen saturation and blood pressure for a simulated patient. (b) A pulse oximeter with a finger sensor. Monitors show single readings; the nurse looks at the trend over time. (credit: (b) “Pulse oximeter” by Glynda Rees Doyle and Jodie Anita McCutcheon/BCcampus, CC BY 4.0)

Figure 6.2 (Ch. 6): Raised red welts on light skin during a skin reaction, similar to hives. On darker skin, redness can be harder to see. (credit: “Rash” by Enochlau/Wikimedia Commons, CC BY-SA 3.0)

Figure 6.3 (Ch. 6): An epinephrine autoinjector held in the fist, with the blue safety release at the top and the orange tip pointing down toward the outer thigh. (credit: “Adrenalina autoinyector9” by AngelHM/Wikimedia Commons, CC BY-SA 4.0)

Figure 6.4 (Ch. 6): A non-rebreather mask with its reservoir bag, used to give high-concentration oxygen as ordered. (credit: “Non re-breather mask” by Glynda Rees Doyle and Jodie Anita McCutcheon/BCcampus, CC BY 4.0)

Figure 7.1 (Ch. 7): An incentive spirometer, which encourages slow, deep breaths after surgery.

Figure 7.2 (Ch. 7): A surgical team at work in an operating room. Before the first incision, the team pauses for the time-out. (credit: “AfS surgical team at the operating room” by Almondbite3/Wikimedia Commons, CC BY-SA 4.0)

Figure 7.3 (Ch. 7): A nurse opens the package of a sterile indwelling urinary catheter. A catheter is inserted only on an order and removed as early as possible. (credit: “Choose smallest catheter size possible” by Glynda Rees Doyle and Jodie Anita McCutcheon/BCcampus, CC BY 4.0)

Figure 7.4 (Ch. 7): A surgical incision closed with staples, 7 days after shoulder surgery. (credit: “Surgical staples2” by Llywrch/Wikimedia Commons, CC BY-SA 2.5)

Figure 8.1 (Ch. 8): Placing a hearing aid. Glasses and hearing aids that are in use, clean and working help prevent delirium and falls, and help the person take part in care.

Figure 8.2 (Ch. 8): A two-wheeled folding walker used to support balance and safe mobilization in hospital and at home. (credit: “Walker. frame” by High Plains Drifter/Wikimedia Commons, Public domain)

Figure 8.3 (Ch. 8): A hip protector: fitted underwear with a pad over the outer hip to cushion a fall. Hip protectors can be considered for people at risk of hip fracture after a discussion of benefits and drawbacks. (credit: “AHIP Protector” by Lkshlzr/Wikimedia Commons, CC BY-SA 3.0)

Figure 9.1 (Ch. 9): Cancer cells under the microscope (squamous cell carcinoma of the skin). In this poorly differentiated, high-grade example, the cells look very different from normal skin cells and grow into the surrounding tissue. (credit: “Micrograph of clear-cell squamous-cell carcinoma” by Valerie R. Yanofsky, Stephen E. Mercer and Robert G. Phelps/Wikimedia Commons, CC BY 4.0)

Figure 9.2 (Ch. 9): A mammogram, the breast screening test, labelled to show normal fibroglandular tissue, a calcification and a mass. (credit: “Low intensity mass on mammography MLO view” by Cerevisae/Wikimedia Commons, CC BY-SA 4.0)

Figure 9.3 (Ch. 9): A home stool test kit for bowel cancer screening (Australia's national program, 2022). Provincial programs mail similar kits for a fecal immunochemical test; contents and instructions vary by program. (credit: “Bowel cancer Home Test Kit Instructions and test tubes in Australia, 2022” by Kgbo/Wikimedia Commons, CC BY-SA 4.0)

Figure 9.4 (Ch. 9): A radiation therapist marks a custom mesh mask fitted to a patient model. For radiation to the head or neck, the mask holds the head in the same position for each treatment.

Figure 9.5 (Ch. 9): A single-lumen peripherally inserted central catheter (PICC) before insertion. (credit: “Peripherally inserted central catheter (PICC) with one lumen” by Glynda Rees Doyle and Jodie Anita McCutcheon/BCcampus, CC BY 4.0)

Figure 9.6 (Ch. 9): An implanted port under the skin of the upper chest, shown on a training manikin. (credit: “Chest with ICVC inserted” by Glynda Rees Doyle and Jodie Anita McCutcheon/BCcampus, CC BY 4.0)

Figure 11.1 (Ch. 11): Ventilating with a bag-valve-mask during resuscitation training. In opioid toxicity, supporting breathing comes first while naloxone takes effect.

Figure 11.2 (Ch. 11): A rapid fentanyl test strip and interpretation guide used in community and hospital harm-reduction drug checking (one red line = positive for fentanyl; two red lines = negative). (credit: “Fentanyl-test-strip” by WikiLinuz/Wikimedia Commons, CC BY-SA 4.0)

Figure 11.3 (Ch. 11): A harm reduction table at a community event in Portland, Oregon, offering free naloxone and fentanyl test strips. (credit: “Harm Reduction Drug Testing Table” by Sarahmirk/Wikimedia Commons, CC BY-SA 4.0)

Figure 11.4 (Ch. 11): A public needle disposal box in a parking lot in Denver, Colorado. Safe disposal sites for used needles are part of harm reduction services. (credit: “Needle disposal box” by Jeffrey Beall/Wikimedia Commons, CC BY 4.0)

Figure 12.1 (Ch. 12): The main structures of the respiratory system, from the nose and mouth to the lungs and diaphragm. (credit: Figure 22.2, “Major Respiratory Structures,” in Anatomy and Physiology 2e by J. Gordon Betts et al./OpenStax, CC BY-NC-SA 4.0)

Figure 12.2 (Ch. 12): The respiratory zone: bronchioles end in alveolar ducts and clusters of alveoli, each wrapped in capillaries where gas exchange takes place. (credit: Figure 22.10, “Respiratory Zone,” in Anatomy and Physiology 2e by J. Gordon Betts et al./OpenStax, CC BY-NC-SA 4.0)

Figure 12.3 (Ch. 12): Clubbing of the fingers with cyanosis of the nail beds. On darker skin, cyanosis may look grey rather than blue. (credit: modification of “Showing bilateral grade III clubbing with cyanosis of the extremities” by Twayana et al./BMC Research Notes, CC BY 4.0)

Figure 12.4 (Ch. 12): Listening to the lungs from the back, on bare skin, comparing side to side.

Figure 12.5 (Ch. 12): A nasal cannula, the most common low-flow oxygen device. (credit: “Nasal cannula” by Glynda Rees Doyle and Jodie Anita McCutcheon/BCcampus, CC BY 4.0)

Figure 12.6 (Ch. 12): (a) A simple face mask. (b) A Venturi mask; the colour-coded valve sets the oxygen concentration. (credit: (a) “Simple face mask” and (b) “Venturi mask” by Glynda Rees Doyle and Jodie Anita McCutcheon/BCcampus, CC BY 4.0)

Figure 12.7 (Ch. 12): A high-flow nasal cannula system on a pole stand, with an oxygen–air blender, a heated humidifier and heated tubing. Hospital policy decides where it is used. (credit: “High Flow Nasal Cannula Classic” by BreathDriver/Wikimedia Commons, CC BY-SA 4.0)

Figure 12.8 (Ch. 12): Home oxygen equipment: (a) an oxygen concentrator, which runs on electricity; (b) a portable oxygen cylinder with a regulator. (credit: (a) “Invacare Perfecto 2 Oxygen Concentrator” by BrokenSphere/Wikimedia Commons, CC BY-SA 3.0)

Figure 12.9 (Ch. 12): Oral suctioning with a rigid Yankauer suction tip on a manikin. (credit: “Suctioning with a yankauer” by Glynda Rees Doyle and Jodie Anita McCutcheon/BCcampus, CC BY 4.0)

Figure 12.10 (Ch. 12): Tracheostomy equipment, from left: obturator, cuffed tube, uncuffed tube and tracheal dilators. (credit: “Obturator, cuffed tracheostomy tube, non-cuffed tracheostomy tube, tracheal dilators” by Glynda Rees Doyle and Jodie Anita McCutcheon/BCcampus, CC BY 4.0)

Figure 13.1 (Ch. 13): Chest X-ray of lobar pneumonia. Consolidation fills the right middle lobe, the white area beside the right heart border (on the viewer's left).

Figure 13.2 (Ch. 13): Influenza A (H1N1) virus particles, coloured blue, seen with a transmission electron microscope.

Figure 13.3 (Ch. 13): Mycobacterium tuberculosis bacteria seen with a scanning electron microscope, magnified about 15,500 times.

Figure 13.4 (Ch. 13): A room pressure monitor beside a negative-pressure isolation room. The green "normal" display shows that air is flowing into the room; the nurse checks it as policy directs and reports an alarm. (credit: “Joondalup Hospital negative pressure room” by Orderinchaos/Wikimedia Commons, CC BY-SA 4.0)

Figure 13.5 (Ch. 13): Three things an N95 respirator needs to protect the wearer: it is put on and worn correctly, it seals snugly against the face, and its filter captures more than 95% of particles. (credit: “Three Key Factors Required for a Respirator to be Effective” by Centers for Disease Control and Prevention/NIOSH, public domain)

Figure 13.6 (Ch. 13): Radon detectors from a home test kit. Because radon has no colour or smell, testing is the only way to know a home's level.

Figure 13.7 (Ch. 13): A packaged thoracentesis kit: a drainage bag and tubing, syringes, and the needle and catheter used to drain pleural fluid. (credit: “ThoracentesisEquip” by James Heilman, MD/Wikimedia Commons, CC BY-SA 4.0)

Figure 14.1 (Ch. 14): The mouthpiece and flow sensor of a hospital pulmonary function testing system, used for spirometry and related breathing tests. (credit: “Device for Spirometry or Body Plethysmography 02” by Joe Mabel/Wikimedia Commons, CC BY-SA 3.0)

Figure 14.2 (Ch. 14): A peak flow meter. The patient blows into it in a short, sharp blow, and a marker moves along the scale to show the peak expiratory flow.

Figure 14.3 (Ch. 14): Smoke from the June 2023 wildfires in Quebec over New York City. Wildfire smoke can travel far from the fires and trigger asthma attacks. (credit: “Wildfire Smoke” by Marc A. Hermann/Metropolitan Transportation Authority, CC BY 2.0)

Figure 14.4 (Ch. 14): Three dry powder inhalers: a Turbuhaler, an Accuhaler (sold in Canada as Diskus) and an Ellipta. Each is loaded differently, so the nurse checks technique with the patient's own device. (credit: “Dry powder inhalers” by Brett Montgomery/Wikimedia Commons, CC BY-SA 4.0)

Figure 14.5 (Ch. 14): A cut slice of lung with centrilobular emphysema, the pattern typical of smoking: many small spaces where alveolar walls have been destroyed, lined with black carbon deposits. The specimen number on the ruler is pixelated. (credit: modification of “Centrilobular emphysema 865 lores” by Edwin P. Ewing, Jr./Centers for Disease Control and Prevention, public domain)

Figure 14.6 (Ch. 14): A nicotine patch on the upper arm. It gives a steady dose of nicotine through the skin; a short-acting form such as gum or a lozenge can be added for cravings. (credit: “Nicoderm” by RegBarc/Wikimedia Commons, CC BY 2.5)

Figure 14.7 (Ch. 14): A home CPAP machine with its tubing and mask. People who use CPAP at home are encouraged to bring their machine to hospital and use it whenever they sleep. (credit: “ResMed CPAP machine and mask” by Infrogmation/Wikimedia Commons, CC BY-SA 4.0)

Figure 15.1 (Ch. 15): Non-invasive ventilation through a full face mask that covers the nose and mouth, connected to a ventilator. This is a posed demonstration; the person's eyes are pixelated. (credit: modification of “BIPAP” by James Heilman, MD/Wikimedia Commons, CC BY-SA 4.0)

Figure 15.2 (Ch. 15): An endotracheal tube in a teaching model of the airway. The tube passes through the mouth into the trachea, and its inflated cuff seals the trachea around it. (credit: “Endotracheal tube” by John Campbell/Flickr, public domain)

Figure 15.3 (Ch. 15): A BC Emergency Health Services critical care helicopter on the rooftop helipad of Vancouver General Hospital. (credit: “BCEHSHeli2017” by James Heilman, MD/Wikimedia Commons, CC BY-SA 4.0)

Figure 15.4 (Ch. 15): Chest X-ray of a large left pneumothorax, labelled: no lung markings in the air-filled space, the collapsed left lung, and the mediastinum shifted to the right. A shift like this, with signs of shock, points to tension pneumothorax, which is treated at once without waiting for an X-ray. (credit: “X-ray of pneumothorax signs” by Karthik Easvur/Wikimedia Commons, CC BY-SA 3.0)

Figure 15.5 (Ch. 15): A chest drainage unit with its parts labelled. (credit: “Chest tube drainage system with labelled parts” by Glynda Rees Doyle and Jodie Anita McCutcheon/BCcampus, CC BY 4.0)

Figure 15.6 (Ch. 15): A portable digital chest drainage unit at the bedside. It applies suction electronically and measures air leak continuously. (credit: “P4053296 logo” by TKiefer/Wikimedia Commons, CC BY-SA 4.0)

Figure 16.1 (Ch. 16): The inside of the heart, front view: the four chambers, the four valves and the great vessels. (credit: Figure 19.9, “Internal Structures of the Heart,” in Anatomy and Physiology 2e by J. Gordon Betts et al./OpenStax, CC BY-NC-SA 4.0)

Figure 16.2 (Ch. 16): The coronary arteries and cardiac veins on the surface of the heart, front view (top) and back view (bottom). (credit: Figure 19.15, “Coronary Circulation,” in Anatomy and Physiology 2e by J. Gordon Betts et al./OpenStax, CC BY-NC-SA 4.0)

Figure 16.3 (Ch. 16): The conduction system of the heart, from the sinoatrial (SA) node through the atrioventricular (AV) node and bundle of His to the bundle branches and Purkinje fibres. (credit: Figure 19.18, “Conduction System of the Heart,” in Anatomy and Physiology 2e by J. Gordon Betts et al./OpenStax, CC BY-NC-SA 4.0)

Figure 16.4 (Ch. 16): A normal ECG cycle with its waves, intervals and segments labelled. (credit: Figure 19.23, “Electrocardiogram,” in Anatomy and Physiology 2e by J. Gordon Betts et al./OpenStax, CC BY-NC-SA 4.0)

Figure 16.5 (Ch. 16): Where to listen to the heart: the aortic, pulmonic, tricuspid and mitral areas. (credit: “2030 Stethoscope Placement” by OpenStax College/Wikimedia Commons, CC BY 3.0)

Figure 16.6 (Ch. 16): A 12-lead ECG in normal sinus rhythm. Each row shows four leads; the long strip along the bottom is lead II. (credit: “Normal sinus rhythm” by LITFL/Life in the Fast Lane, CC BY-NC-SA 4.0)

Figure 16.7 (Ch. 16): Placement of the six chest (precordial) electrodes, V1 to V6, for a 12-lead ECG. The dotted line marks the left midclavicular line. (credit: “ECG lead positioning” by LITFL/Life in the Fast Lane, CC BY-NC-SA 4.0)

Figure 16.8 (Ch. 16): A 12-lead ECG showing sinus bradycardia: a P wave before every QRS complex, at a slow rate. (credit: “Sinus bradycardia” by LITFL/Life in the Fast Lane, CC BY-NC-SA 4.0)

Figure 16.9 (Ch. 16): A 12-lead ECG showing sinus tachycardia at about 150 per minute. At fast rates the P waves can merge into the T waves before them. (credit: “Sinus tachycardia” by LITFL/Life in the Fast Lane, CC BY-NC-SA 4.0)

Figure 16.10 (Ch. 16): A 12-lead ECG showing ventricular bigeminy: a wide, early premature ventricular contraction (PVC) after every normal beat. (credit: “ECG Premature Ventricular Complex (PVC) Bigeminy” by LITFL/Life in the Fast Lane, CC BY-NC-SA 4.0)

Figure 16.11 (Ch. 16): Rhythm strip of monomorphic ventricular tachycardia: a fast, regular rhythm of wide QRS complexes that look alike. (credit: “Monomorphic ventricular tachycardia” by LITFL/Life in the Fast Lane, CC BY-NC-SA 4.0)

Figure 16.12 (Ch. 16): Rhythm strip of ventricular fibrillation: chaotic, irregular waves with no identifiable P waves, QRS complexes or T waves. (credit: “VF rhythm strip” by LITFL/Life in the Fast Lane, CC BY-NC-SA 4.0)

Figure 16.13 (Ch. 16): Rhythm strip in which a slow rhythm ends in a flat line (asystole). The nurse confirms that the electrodes are attached and that the patient has no pulse. (credit: Figure 12.18 in Medical-Surgical Nursing by OpenStax, CC BY-NC-SA 4.0)

Figure 16.14 (Ch. 16): A 12-lead ECG showing atrial fibrillation with a rapid ventricular response: an irregularly irregular rhythm with no clear P waves. (credit: “AF with rapid ventricular response” by LITFL/Life in the Fast Lane, CC BY-NC-SA 4.0)

Figure 16.15 (Ch. 16): A 12-lead ECG showing atrial flutter with 4:1 block: sawtooth flutter waves, with one QRS complex for every four flutter waves. (credit: “Atrial flutter with 4:1 block” by LITFL/Life in the Fast Lane, CC BY-NC-SA 4.0)

Figure 16.16 (Ch. 16): Rhythm strip showing first-degree AV block: every P wave is followed by a QRS complex, but the PR interval (marked) is longer than 0.20 seconds. (credit: “Rhythm strip: PR interval prolonged, first-degree AV block” by LITFL/Life in the Fast Lane, CC BY-NC-SA 4.0)

Figure 16.17 (Ch. 16): A 12-lead ECG showing second-degree AV block, Mobitz I (Wenckebach): the PR interval lengthens from beat to beat until a P wave is not conducted and a QRS complex is dropped. (credit: “Mobitz I AV block” by LITFL/Life in the Fast Lane, CC BY-NC-SA 4.0)

Figure 16.18 (Ch. 16): Rhythm strip showing second-degree AV block, Mobitz II: the PR interval stays the same, and the arrows mark P waves that are suddenly not conducted. (credit: “Mobitz II AV block” by LITFL/Life in the Fast Lane, CC BY-NC-SA 4.0)

Figure 16.19 (Ch. 16): Rhythm strip showing complete (third-degree) AV block: P waves (small arrows) at about 100 per minute, unrelated to wide QRS complexes (R) at about 40 per minute. (credit: “Complete heart block” by LITFL/Life in the Fast Lane, CC BY-NC-SA 4.0)

Figure 16.20 (Ch. 16): Chest X-ray of a single-chamber permanent pacemaker: the pulse generator under the skin of the upper chest and one lead in the heart. A label in the corner is pixelated. (credit: modification of “VVI Schrittmacher THWZ” by Th. Zimmermann/Wikimedia Commons, CC BY-SA 3.0 DE)

Figure 16.21 (Ch. 16): Anterolateral pad placement: one pad below the right clavicle and one on the left side of the chest, so the current passes through the heart. (credit: “Defib electrode placement” by Owain Davies/Wikimedia Commons, CC BY 3.0)

Figure 16.22 (Ch. 16): A public-access AED in a wall cabinet. (credit: modification of Figure 19.26, “Defibrillators,” in Anatomy and Physiology 2e by J. Gordon Betts et al./OpenStax, CC BY-NC-SA 4.0; panel (a) only)

Figure 17.1 (Ch. 17): Three-dimensional images of the heart built from a coronary computed tomography angiography scan, showing the coronary arteries on its surface. (credit: “Coronary CT Angiography Scan” by Goleisureintl/Wikimedia Commons, CC BY 4.0)

Figure 17.2 (Ch. 17): Three forms of nitroglycerin: an intravenous solution (used in hospital), a sublingual spray and a transdermal patch. (credit: “Nitro” by James Heilman, MD/Wikimedia Commons, CC BY-SA 3.0)

Figure 17.3 (Ch. 17): A 12-lead ECG showing an acute extensive anterior STEMI: ST elevation across the chest leads and in I and aVL, with reciprocal ST depression in the inferior leads. (credit: “Extensive Anterior STEMI (acute)” by LITFL/Life in the Fast Lane, CC BY-NC-SA 4.0)

Figure 17.4 (Ch. 17): A 12-lead ECG showing an inferior STEMI: ST elevation in leads II, III and aVF, with reciprocal ST depression in aVL. (credit: “Inferior STEMI” by LITFL/Life in the Fast Lane, CC BY-NC-SA 4.0)

Figure 17.5 (Ch. 17): An expanded coronary stent holding a narrowed artery open (enlarged view). (credit: “Cobalt Chromium Coronary Stent in Heart” by ETTon/Wikimedia Commons, CC BY-SA 4.0)

Figure 18.1 (Ch. 18): A markedly raised jugular venous pressure: the distended external jugular vein (arrow) runs up the side of the neck. The face was masked by the photographer, and the Commons page records the person's consent. (credit: “Elevated JVP1” by James Heilman, MD/Wikimedia Commons, CC BY-SA 3.0)

Figure 18.2 (Ch. 18): Chest X-ray in heart failure, labelled: an enlarged heart, upper-lobe vessels that are more prominent than usual, Kerley B lines from fluid in the lung tissue, and a small pleural effusion.

Figure 18.3 (Ch. 18): Chest X-ray of a cardiac resynchronization pacemaker: the generator in the upper chest and three leads, one in the right atrium and one in each ventricle. (credit: "CRT-P-THWZ" by Th. Zimmermann/Wikimedia Commons, CC BY-SA 3.0 DE)

Figure 18.4 (Ch. 18): A left ventricular assist device: the pump draws blood from the left ventricle and returns it to the aorta; a driveline through the skin connects it to an external controller and batteries. (credit: "Ventricular assist device" by Madhero88/Wikimedia Commons, CC BY-SA 3.0)

Figure 18.5 (Ch. 18): A mechanical heart valve shown in place in the heart (illustration). Clots can form on its surfaces, so lifelong anticoagulation is needed. (credit: "3D Medical Animation still shot Artificial Heart Valve" by Scientific Animations/Wikimedia Commons, CC BY-SA 4.0)

Figure 18.6 (Ch. 18): Janeway lesions on the palm of a man with staphylococcal endocarditis: small, flat, painless red spots. On darker skin they look purple to dark brown. (credit: "Janeway lesion" by Warfieldian/Wikimedia Commons, CC BY-SA 4.0)

Figure 18.7 (Ch. 18): Echocardiogram showing a vegetation (arrow) on the tricuspid valve in infective endocarditis. (credit: "Endocarditis ultrasound" by Daisuke Koya, Kazuyuki Shibuya, Ryuichi Kikkawa and Masakazu Haneda; derivative work by Materialscientist/Wikimedia Commons, CC BY 2.0)

Figure 18.8 (Ch. 18): A peripherally inserted central catheter (PICC) after removal at the end of two months of treatment, with its hub and securement dressing. (credit: "Peripherally inserted central catheter (PICC or PIC line) after use in a patient for two months 2018 The Netherlands" by Hansmuller/Wikimedia Commons, CC BY-SA 4.0)

Figure 18.9 (Ch. 18): A 12-lead ECG in acute pericarditis, with ST elevation in many leads. Because pericarditis can mimic acute coronary syndrome, the patient with chest pain is assessed for both. (credit: "ECG Pericarditis" by LITFL/Life in the Fast Lane, CC BY-NC-SA 4.0)

Figure 18.10 (Ch. 18): A normal heart compared with hypertrophic cardiomyopathy (thickened muscle) and dilated cardiomyopathy (enlarged chamber with thin, stretched muscle). (credit: "Illustration of an enlarged heart (Cardiomegaly)" by myUpchar/Wikimedia Commons, CC BY-SA 4.0)

Figure 19.1 (Ch. 19): An aneroid sphygmomanometer: an adult cuff with its size label and range marks, a dial gauge and an inflation bulb. The range marks show whether the cuff fits the arm.

Figure 19.2 (Ch. 19): Blood pressure cuffs come in many sizes, from neonatal to large adult and thigh cuffs. A cuff of the wrong size makes readings unreliable, so the arm is measured to choose the size. (credit: "Sizes of blood pressure cuffs" by Chippewa Valley Technical College, CC BY 4.0)

Figure 19.3 (Ch. 19): A foot with peripheral arterial disease: a dry ulcer at the tip of the big toe and thickened nails. (credit: "Peripheral artery disease" by Milorad Dimić (Intermedichbo)/Wikimedia Commons, CC BY-SA 4.0)

Figure 19.4 (Ch. 19): Contrast-enhanced CT of an abdominal aortic aneurysm measuring about 4.8 by 3.8 cm (green measurement lines). (credit: "Contrast-enhanced CT scan demonstrating abdominal aortic aneurysm" by James Heilman, MD/Wikimedia Commons, CC BY-SA 3.0)

Figure 19.5 (Ch. 19): Deep vein thrombosis of the right leg (arrow): the leg is swollen and redder than the other. On darker skin, the change may look darker or purplish, or be hard to see. (credit: "Deep vein thrombosis of the right leg" by James Heilman, MD/Wikimedia Commons, CC BY-SA 3.0)

Figure 19.6 (Ch. 19): Varicose veins: raised, twisted surface veins over the lower leg and ankle.

Figure 19.7 (Ch. 19): Chronic venous insufficiency on darker skin: dark hyperpigmentation and thickened skin above the ankle, with an open venous ulcer. (credit: "Chronic venous insufficiency & Venous ulcer" by Ahmed Shawky Mohammedin, MD (Ashashyou)/Wikimedia Commons, CC BY-SA 4.0)

Figure 19.8 (Ch. 19): Medical compression stockings come in different lengths, strengths and colours; the type is prescribed after an arterial assessment. (credit: "Medizinische Kompressionsstrümpfe" by Enter/Wikimedia Commons, CC BY-SA 3.0)

Figure 20.1 (Ch. 20): Hematopoiesis: one stem cell population in the bone marrow gives rise to two lines. The myeloid line makes red cells, platelets and most white cells; the lymphoid line makes lymphocytes. (credit: Figure 18.4, "Hematopoietic System of Bone Marrow," in Anatomy and Physiology 2e by J. Gordon Betts et al./OpenStax, CC BY-NC-SA 4.0)

Figure 20.2 (Ch. 20): A blood smear in severe iron deficiency anemia: the red cells are small (microcytic) and pale (hypochromic), with wide pale centres. (credit: "Iron-deficiency Anemia, Peripheral Blood Smear" by Ed Uthman/Wikimedia Commons, CC BY 2.0)

Figure 20.3 (Ch. 20): Koilonychia: thin nails that curve up at the edges into a spoon shape, a sign of long-standing iron deficiency. Nail and skin changes are useful cues on every skin tone. (credit: "Koilonychia iron deficiency anemia" by CHeitz/Wikimedia Commons, CC BY 2.0)

Figure 20.4 (Ch. 20): Red blood cells seen with a scanning electron microscope: normal round, dimpled discs and one rigid, crescent-shaped sickle cell. (credit: Janice Haney Carr/Centers for Disease Control and Prevention, public domain)

Figure 20.5 (Ch. 20): Petechiae on the lower leg of a person with immune thrombocytopenia and a very low platelet count. On darker skin, petechiae may look darker than the surrounding skin rather than red, and are easier to find in good light. (credit: "Petechia lower leg" by James Heilman, MD/Wikimedia Commons, CC BY-SA 4.0)

Figure 20.6 (Ch. 20): A myeloblast with an Auer rod, a thin rod in the cell's cytoplasm. Auer rods are a feature of acute myeloid leukemia, and blasts on a smear are often the first clue to leukemia. (credit: "Myeloblast with Auer Rod smear 2009-11-23" by Paulo Henrique Orlandi Mourao/Wikimedia Commons, CC BY-SA 3.0)

Figure 20.7 (Ch. 20): Sites that can be used for bone marrow aspiration and biopsy: the sternum, the tibia, and the posterior and anterior iliac crests. (credit: "Site for procedure of Bone Marrow" by Scientific Animations (scientificanimations.com)/Wikimedia Commons, CC BY-SA 4.0)

Figure 20.8 (Ch. 20): A unit of red blood cell concentrate connected to a blood administration set with an in-line filter. The nurse checks the unit tag against the patient and the order at the bedside before starting. (credit: "Red blood cells and blood IV tubing" by Glynda Rees Doyle and Jodie Anita McCutcheon/BCcampus, CC BY 4.0)

Figure 21.1 (Ch. 21): The lymphatic system. Lymphocytes are made in the bone marrow, T cells mature in the thymus, and both gather in the lymph nodes, spleen and tonsils, where they meet antigens carried in lymph and blood. (credit: Figure 21.2, “Anatomy of the Lymphatic System,” in Anatomy and Physiology 2e by J. Gordon Betts et al./OpenStax, CC BY-NC-SA 4.0)

Figure 21.2 (Ch. 21): Skin prick testing on the forearms. Each pen mark labels one allergen, and a raised, red wheal at a site suggests sensitization to that allergen; redness is harder to judge on darker skin. A positive test is interpreted with the history.

Figure 21.3 (Ch. 21): Herpes zoster (shingles): clustered red papules and vesicles in a band that follows one or two dermatomes on one side of the trunk. (credit: CDC/K.L. Herrmann, Public Health Image Library, public domain)

Figure 21.4 (Ch. 21): The structure of HIV: an outer envelope with docking proteins that attach to the CD4 receptor on a host cell, and a capsid holding the viral RNA and the enzymes reverse transcriptase and integrase. (credit: National Institute of Allergy and Infectious Diseases, public domain)

Figure 21.5 (Ch. 21): The HIV replication cycle. Antiretroviral drug classes act at different steps: entry, reverse transcription, integration and maturation by protease (section 21.5). (credit: “HI-Virus Replication Cycle” by NIAID/Wikimedia Commons, CC BY 2.0)

Figure 21.6 (Ch. 21): Oral candidiasis (thrush): creamy white patches on red, inflamed mucosa. Unlike food debris, the patches do not rinse away. (credit: Centers for Disease Control and Prevention, Public Health Image Library, public domain)

Figure 21.7 (Ch. 21): Kaposi sarcoma on the skin of a person with advanced HIV: raised, red-purple patches and nodules. On darker skin the lesions may look brown or black. (credit: unknown author/Wikimedia Commons, public domain)

Figure 22.1 (Ch. 22): A point-of-care glucose meter with lancets, test strips and cotton balls. The meter must be one the laboratory approves, and the nurse follows the unit's quality-control routine. (credit: “A blood glucose monitoring machine with cotton balls, lancets, and reagent strips” by Glynda Rees Doyle and Jodie Anita McCutcheon/BCcampus, CC BY 4.0)

Figure 22.2 (Ch. 22): An intermittently scanned (flash) glucose sensor on the upper arm. Holding the reader or a phone near the sensor shows the current glucose and its trend. (credit: “FreeStyle libre am Oberarm und Auslesegerät-4” by Thirunavukkarasye-Raveendran/Wikimedia Commons, CC BY 4.0)

Figure 22.3 (Ch. 22): An insulin pen with a pen needle and its outer cap. A new needle is attached for every injection, and the pen is labelled for one patient only. The round device on the left is an injection port, which some people use to reduce skin punctures. (credit: “I-Port Advance and insulin pen (Novorapid), with needle cover” by Marius Vassnes/Wikimedia Commons, CC BY-SA 4.0)

Figure 22.4 (Ch. 22): An adult with type 1 diabetes wearing an insulin pump on his waistband, with tubing to an infusion set on the abdomen, and a continuous glucose sensor. Pumps deliver rapid-acting insulin continuously, plus doses for meals. (credit: “Diabetic Type 1 adult man with insulin pump and CGM sensor” by Medtd1/Wikimedia Commons, CC BY-SA 4.0)

Figure 22.5 (Ch. 22): A foot ulcer over a Charcot deformity, a collapse of the midfoot bones that can follow neuropathy. The ulcer sits where pressure falls on a foot that has lost sensation. (credit: “Diabetic Charcot Foot Deformity” by Medicalpal/Wikimedia Commons, CC BY-SA 4.0)

Figure 22.6 (Ch. 22): An arterial ulcer for comparison: a round, punched-out wound on the foot with little drainage, caused by poor blood flow rather than pressure. Many people with diabetes have both neuropathy and arterial disease (Chapter 19). (credit: “Arterial ulcer peripheral vascular disease” by Jonathan Moore/Wikimedia Commons, CC BY 3.0)

Figure 23.1 (Ch. 23): The main endocrine glands. The hypothalamus and pituitary at the base of the brain control the thyroid, adrenal cortex and gonads through feedback loops; the parathyroid glands respond directly to blood calcium. (credit: Figure 17.2, “Endocrine System,” in Anatomy and Physiology 2e by J. Gordon Betts et al./OpenStax, CC BY-NC-SA 4.0)

Figure 23.2 (Ch. 23): Ultrasound of the thyroid, viewed in cross-section: a fluid-filled cyst and a small nodule with bright calcifications. Ultrasound features help decide which nodules need fine-needle aspiration. (credit: “Ultrasound of thyroid showing right lower pole cyst and a calcified nodule” by Cerevisae/Wikimedia Commons, CC BY-SA 4.0)

Figure 23.3 (Ch. 23): A healing scar 2 months after total thyroidectomy. The incision lies low across the front of the neck.

Figure 23.4 (Ch. 23): Striae in a person with Cushing syndrome. On lighter skin, new striae are often red-purple, as here; on darker skin they are often brown to black, or may look pale. (credit: “Striae” by PanaromicTiger/Wikimedia Commons, CC BY-SA 3.0)

Figure 23.5 (Ch. 23): MRI of the head from the side, with an arrow marking a pituitary microadenoma, a tumour smaller than 1 cm. MRI is the main imaging test for pituitary tumours. (credit: “Adenome hypophyse esp” by Yakafaucon/Wikimedia Commons, CC BY-SA 4.0)

Figure 24.1 (Ch. 24): The digestive system: the alimentary canal from mouth to anus and the accessory organs (salivary glands, liver, gallbladder and pancreas). (credit: Figure 23.2, “Components of the Digestive System,” in Anatomy and Physiology 2e by J. Gordon Betts et al./OpenStax, CC BY-NC-SA 4.0)

Figure 24.2 (Ch. 24): Supplies gathered for nasogastric tube insertion, including the tube, lubricant, a securement device, pH strips, a large syringe and water for the patient to sip. Placement is confirmed before the tube is first used, as described later in this section. (credit: “Gather supplies” by Glynda Rees Doyle and Jodie Anita McCutcheon/BCcampus, CC BY 4.0)

Figure 24.3 (Ch. 24): Equipment for placing a percutaneous endoscopic gastrostomy (PEG) tube: the tube with its internal disc (bumper), which holds it inside the stomach, an introducer needle and a guidewire. (credit: “PEG tube kit” by Gilo1969/Wikimedia Commons, CC BY-SA 3.0)

Figure 24.4 (Ch. 24): An enteral feeding pump with its feeding set. Enteral equipment is kept apart from IV lines, and ENFit connectors are designed so the two cannot be joined. (credit: “Enteral feeding pumps” by Ahmed Shawky Mohammedin, MD (Ashashyou)/Wikimedia Commons, CC BY-SA 3.0)

Figure 24.5 (Ch. 24): A three-chamber parenteral nutrition bag. Amino acids, dextrose and lipid are kept in separate compartments until the seals between them are opened and the contents mixed, just before use. (credit: “Smofkabiven Zentral Bag” by Ibrahim Husain Meraj/Wikimedia Commons, CC BY-SA 4.0)

Figure 24.6 (Ch. 24): Roux-en-Y gastric bypass anatomy: a small proximal stomach pouch is created with surgical staples and anastomosed directly to a Roux limb of the jejunum, bypassing the distal stomach and duodenum. (credit: “Blausen 0776 Roux-En-Y 01” by BruceBlaus/Wikimedia Commons, CC BY 3.0)

Figure 25.1 (Ch. 25): An upright abdominal X-ray in small bowel obstruction: dilated loops with many air-fluid levels. X-rays like this may be taken, but CT is the preferred test because it shows the level and cause and signs of ischemia. (credit: "Upright X-ray demonstrating small bowel obstruction" by James Heilman, MD/Wikimedia Commons, CC BY-SA 3.0)

Figure 25.2 (Ch. 25): A colon polyp seen during colonoscopy. Removing adenomatous polyps during colonoscopy can prevent them from becoming cancer.

Figure 25.3 (Ch. 25): A permanent colostomy after surgery for rectal cancer (inset). The end of the descending colon is brought out through the left lower abdomen, where stool is collected in a pouch. (credit: National Cancer Institute, public domain)

Figure 25.4 (Ch. 25): A healthy ileostomy stoma: moist and red, with the skin barrier cut to fit closely around it. (credit: "Ostomy wafer being worn by an ileostomy patient" by Eric Polsinelli (VeganOstomy)/Wikimedia Commons, CC BY 4.0)

Figure 25.5 (Ch. 25): A large parastomal hernia around a colostomy in an older man: the abdominal wall bulges around the stoma, under the pouch. A flexible pouching system is preferred over a firm, convex one.

Figure 25.6 (Ch. 25): A one-piece, drainable pouch over an ileostomy. The pouch is emptied when it is about one-third full. (credit: "Ileostomy with bag" by Remedios44/Wikimedia Commons, CC BY-SA 4.0)

Figure 26.1 (Ch. 26): The liver, gallbladder and pancreas, with the ducts that carry bile and pancreatic juice to the duodenum. The image is cropped to the upper abdomen. (credit: modification of Figure 23.24, "Accessory Organs," in Anatomy and Physiology 2e by J. Gordon Betts et al./OpenStax, CC BY-NC-SA 4.0)

Figure 26.2 (Ch. 26): Yellow sclerae in jaundice. The sclerae are a reliable place to look for jaundice on every skin tone. The image is cropped to the eye. (credit: modification of "Jaundice" by OpenRN/Nursing Skills, 2e, CC BY 4.0)

Figure 26.3 (Ch. 26): Spider angiomas on lighter skin: a red central point with fine vessels radiating outward. (credit: "SpiderAngioma" by James Heilman, MD/Wikimedia Commons, CC BY-SA 4.0)

Figure 26.4 (Ch. 26): Palmar erythema in a 79-year-old woman: redness of the palms, most marked at the base of the thumb and little finger. (credit: "Palmar erythema" by Jmarchn/Wikimedia Commons, CC BY-SA 3.0)

Figure 26.5 (Ch. 26): Massive ascites from portal hypertension in cirrhosis: a tense, rounded abdomen with prominent surface veins. (credit: "Hepaticfailure" by James Heilman, MD/Wikimedia Commons, CC BY-SA 3.0)

Figure 26.6 (Ch. 26): Abdominal paracentesis: a needle or catheter in the abdominal wall drains ascitic fluid into a collection container. (credit: "Blausen 0004 AbdominalParacentesis" by BruceBlaus/Wikimedia Commons, CC BY 3.0)

Figure 26.7 (Ch. 26): Esophageal varices and endoscopic band ligation: elastic bands are placed around the enlarged veins to stop or prevent bleeding. (credit: "Endoscopic Banding for Esophageal Varices" by Kel898/Wikimedia Commons, CC BY-SA 4.0)

Figure 26.8 (Ch. 26): Gallstones removed from one patient, on a 1 mm grid. (credit: "Human gallstones 2015 G1" by George Chernilevsky/Wikimedia Commons, CC BY-SA 4.0)

Figure 26.9 (Ch. 26): Endoscopic retrograde cholangiopancreatography (ERCP): the endoscope enters through the mouth and passes through the stomach to the duodenum, where instruments reach the common bile duct. (credit: "ERCP" by Drus1a/Wikimedia Commons, CC BY-SA 4.0)

Figure 27.1 (Ch. 27): A frontal section of the left kidney: the outer cortex, the pyramids of the medulla, and the calyces and renal pelvis that collect urine into the ureter. (credit: Figure 25.8, "Left Kidney," in Anatomy and Physiology 2e by J. Gordon Betts et al./OpenStax, CC BY-NC-SA 4.0)

Figure 27.2 (Ch. 27): A nephron and its blood supply. Blood is filtered in the glomerulus, and the tubule then reclaims water and solutes into the peritubular capillaries; what remains flows on as urine. (credit: Figure 25.10, "Blood Flow in the Nephron," in Anatomy and Physiology 2e by J. Gordon Betts et al./OpenStax, CC BY-NC-SA 4.0)

Figure 27.3 (Ch. 27): Two urine dipsticks: one with colour changes on several pads (left) beside one with little reaction (right). Each pad is compared with the colour chart on the container at the time stated. (credit: "Comp.Urine.Test.Strip" by J3D3/Wikimedia Commons, CC BY-SA 3.0)

Figure 27.4 (Ch. 27): Uremic frost on the forehead and scalp of a young Black man: fine white crystals left on the skin as sweat evaporates. It is a rare sign of severe, untreated uremia. (credit: "Uremic frost on forehead and scalp of young Afro-Caribbean male" by Fythrion/Wikimedia Commons, CC BY-SA 3.0)

Figure 27.5 (Ch. 27): A hemodialysis machine beside a treatment chair. The blood pump moves blood through the dialyzer, and the screen shows pressures, flow and fluid removal. (credit: "Hemodialysis machine INNOVA" by Vitaly Pospelov (Виталий Поспелов) at Russian Wikipedia/Wikimedia Commons, CC BY-SA 3.0)

Figure 27.6 (Ch. 27): Peritoneal dialysis: sterile dialysate flows through an indwelling catheter into the peritoneal cavity, where water and uremic solutes diffuse across the semipermeable peritoneal membrane before the effluent is drained. (credit: "Peritoneal dialysis" by Manu5 [Scientific Animations]/Wikimedia Commons, CC BY-SA 4.0)

Figure 28.1 (Ch. 28): Emptying a urinary drainage bag: the spout drains into a separate measuring container without touching it, and the bag stays below the level of the bladder. (credit: "Empty the Urinary Drainage Bag" by BruceBlaus/Wikimedia Commons, CC BY-SA 4.0)

Figure 28.2 (Ch. 28): Non-contrast CT showing a stone in the upper right ureter (the bright white spot) causing mild blockage. CT is used carefully, preferably at a low dose. (credit: "KidneyStone" by James Heilman, MD/Wikimedia Commons, CC BY-SA 3.0)

Figure 28.3 (Ch. 28): Kidney stone fragments after shock wave lithotripsy, beside a millimetre scale. Patients may be asked to strain their urine so that fragments can be analyzed. (credit: "Kidney stones" by Arconsoli/Wikimedia Commons, CC BY-SA 4.0)

Figure 28.4 (Ch. 28): Comparison of a normal prostate and urethra (top) with benign prostatic hyperplasia (bottom), in which nodular enlargement of the prostate compresses the prostatic urethra and obstructs bladder outflow. (credit: "Benign Prostatic Hyperplasia (BPH)" by BruceBlaus/Wikimedia Commons, CC BY-SA 4.0)

Figure 28.5 (Ch. 28): Visible blood in the urine (gross hematuria), with a dipstick that is positive for blood. Visible hematuria in an adult is always reported and investigated.

Figure 35.10 (Ch. 35): Cellulitis of the toes and forefoot, with spreading redness and swelling of the skin.

Figure 35.11 (Ch. 35): Classification of burn depth: superficial (first degree, affecting the epidermis), partial thickness (second degree, extending into the dermis with blisters), and full thickness (third degree, destroying all epidermal and dermal layers into subcutaneous tissue). (credit: “Figure 8.14, Burn Depth” by Persian Poet Gal/OpenStax, Clinical Nursing Skills, CC BY 3.0)] A **superficial burn** involves only the epidermis. A **partial-thickness burn** extends into the dermis: a superficial partial-thickness burn involves the upper dermis, and a deep partial-thickness burn reaches deeper into it. A **full-thickness burn** destroys the epidermis and the whole dermis and can extend to fat, muscle, tendon or bone (Wallace et al., 2025). Older terms number these as first, second and third degree, with fourth degree used when muscle or bone is involved (Trauma New Brunswick, 2025). Depth is hard to judge: even burn experts are accurate only 64% to 76% of the time, so early estimates are rechecked (Wallace et al., 2025). Healed superficial partial-thickness burns can stay sensitive to sun, cold and friction for months, and they may itch (Wallace et al., 2025). Redness and blanching can be harder to see on darker skin, so the nurse also notes blisters, moisture, texture, capillary refill and sensation (Black & Simende, 2020).

Figure 35.12 (Ch. 35): Body regions used in the adult Wallace rule of nines: the head and neck and each upper limb are 9% each, the anterior trunk, posterior trunk and each lower limb are 18% each (9% front and 9% back), and the perineum is 1%.

Figure 35.13 (Ch. 35): Acral lentiginous melanoma: (a) a large asymmetric pigmented lesion with irregular borders and varied brown-to-black colour on the sole of the foot; (b) subungual melanoma of the thumb. Checking the palms, soles and nail beds is part of a complete skin assessment across all skin tones. (credit: (a) “Photography of a large acral lentiginous melanoma” by José C. C. Xavier-Júnior et al./Diagnostic Pathology, CC BY 4.0; (b) “Melanoma of thumb” by Wawjak/Wikimedia Commons, CC BY 4.0)

Figure 35.14 (Ch. 35): Herpes zoster (shingles): clustered vesicles on an erythematous base following a single unilateral dermatome on the back without crossing the midline. (credit: “Herpes Zoster Rash” by BruceBlaus/Wikimedia Commons, CC BY-SA 4.0)

Figure 36.1 (Ch. 36): Cross-sectional anatomy of the human eye showing refractive structures (cornea, lens), anterior and posterior chambers, vascular uvea (iris, ciliary body, choroid), neurosensory retina and optic nerve. (credit: “Figure 14.15, Structure of the Eye” by J. Gordon Betts et al./OpenStax, Anatomy and Physiology 2e, CC BY-NC-SA 4.0)

Figure 36.2 (Ch. 36): A Snellen letter chart used to measure distance visual acuity. (credit: “Snellen Chart” by Creative magnet/Wikimedia Commons, CC BY-SA 4.0)

Figure 36.3 (Ch. 36): Slit-lamp view of a dense cataract clouding the crystalline lens behind the pupil. (credit: “Cataract in human eye” by Rakesh Ahuja, MD/Wikimedia Commons, CC BY-SA 3.0)

Figure 36.4 (Ch. 36): Instilling eye drops: the patient looks up while the nurse gently pulls down the lower lid to form a pocket and holds the dropper tip clear of the eye and eyelashes. (credit: “Instilling eye medication” by British Columbia Institute of Technology (BCIT)/BCcampus, CC BY 4.0)

Figure 36.5 (Ch. 36): Acute angle-closure glaucoma of the right eye, showing conjunctival redness, corneal haziness and a mid-dilated, non-reactive pupil (cropped to the affected eye). (credit: modification of “Acute angle closure glaucoma” by James Heilman, MD/Wikimedia Commons, CC BY-SA 3.0)

Figure 36.6 (Ch. 36): Retinal fundus photograph showing clustered yellow drusen in the macula in age-related macular degeneration. (credit: “MacularDegenerationFundus” by Tmhlee/Wikimedia Commons, CC BY-SA 3.0)

Figure 36.7 (Ch. 36): Prominent hyphema filling the anterior chamber in front of the iris, with surrounding ciliary injection. (credit: “12886 2014 Article 436 Fig1 HTML” by Yoko Okunuki et al./BMC Ophthalmology, CC BY 4.0)

Figure 36.8 (Ch. 36): Anatomy of the human ear showing the external ear, the air-filled middle ear containing the auditory ossicles (malleus, incus, stapes) and tympanic membrane, and the fluid-filled inner ear (cochlea and vestibular apparatus). (credit: “Figure 14.5, Ear Structures” by J. Gordon Betts et al./OpenStax, Anatomy and Physiology 2e, CC BY-NC-SA 4.0)

Figure 36.9 (Ch. 36): Otoscopic view of a right tympanic membrane showing the translucent pearly grey eardrum and landmarks (the small black dot is India ink placed to demonstrate normal outward migration of the canal epithelium). (credit: “Ink Dot on the surface of the tympanic membrane 1 week later” by Michael Hawke, MD/Wikimedia Commons, CC BY 4.0)

Figure 36.10 (Ch. 36): An external behind-the-ear cochlear implant sound processor and its round magnetic transmitting headpiece, which sits over the internal receiver under the scalp. (credit: “Advanced Bionics cochlear implant processor BTE (first-generation behind-the-ear processor)” by MikeCore9918/Wikimedia Commons, CC BY-SA 4.0)

Figure 36.11 (Ch. 36): A behind-the-ear hearing aid with tubing leading to an earmold in the ear canal. (credit: “Behind-the-Ear Hearing Aid grayscale photo” by Steve Johnson/Wikimedia Commons, CC BY 2.0)

Figure 36.12 (Ch. 36): Instilling ear drops in an adult: the patient lies with the affected ear up while the nurse gently pulls the pinna upward and backward to straighten the ear canal and holds the dropper tip clear of the skin. BACK MATTER — ALPHABETICAL SUBJECT & CONCEPT INDEX *Index*

IX Comprehensive Subject & Clinical Concept Index

2SLGBTQI+ — Ch. 2, p. 35
4AT — Ch. 8, p. 206
5-alpha reductase inhibitor (5-ARI) — Ch. 28, p. 822
A1C — Ch. 22, p. 635
Abdominal Aortic Aneurysm — s. 19.5, p. 538
abdominal aortic aneurysm (AAA) — Ch. 19, p. 538
abdominoperineal resection — Ch. 25, p. 727
abnormal extension — Ch. 30, p. 883
abnormal flexion — Ch. 30, p. 883
abnormal uterine bleeding — Ch. 29, p. 852
abscess — Ch. 35, p. 1040
absolute neutrophil count (ANC) — Ch. 9, p. 234
acanthosis nigricans — Ch. 22, p. 635
acidemia — Ch. 3, p. 67
acidosis — Ch. 3, p. 67
Acid–Base Balance — s. 3.7, p. 67
acquired immunodeficiency syndrome (AIDS) / advanced HIV disease — Ch. 21, p. 601
acral melanoma — Ch. 35, p. 1040
acromegaly — Ch. 23, p. 665
action plan — Ch. 18, p. 504
active offer — Ch. 1, p. 2
active surveillance — Ch. 28, p. 822
Acute and Chronic Pancreatitis — s. 26.6, p. 759
acute angle-closure glaucoma — Ch. 36, p. 1075
acute aortic syndrome — Ch. 19, p. 538
acute chest syndrome — Ch. 20, p. 569
acute cholecystitis — Ch. 26, p. 759
acute colonic pseudo-obstruction — Ch. 25, p. 727
acute coronary syndrome (ACS) — Ch. 17, p. 476
acute decompensated heart failure (ADHF) — Ch. 18, p. 504
acute exacerbation of COPD — Ch. 14, p. 380
acute heart failure — Ch. 18, p. 504
acute hemolytic transfusion reaction — Ch. 20, p. 569
acute HIV infection — Ch. 21, p. 601
acute inflammation — Ch. 4, p. 97
Acute Kidney Injury — s. 27.2, p. 791
acute kidney injury (AKI) — Ch. 27, p. 791
Acute Kidney Injury and Chronic Kidney Disease — Ch. 27, p. 791
acute limb ischemia — Ch. 19, p. 538
acute liver failure (ALF) — Ch. 26, p. 759
acute pain — Ch. 5, p. 125
acute pancreatitis — Ch. 26, p. 759
acute pulmonary edema — Ch. 18, p. 504
Acute Respiratory Distress Syndrome — s. 15.2, p. 409
acute respiratory distress syndrome — Ch. 15, p. 409
Acute Respiratory Failure — s. 15.1, p. 409
acute respiratory failure — Ch. 15, p. 409
Acute Respiratory Failure and Pulmonary Embolism — Ch. 15, p. 409
acute severe ulcerative colitis — Ch. 25, p. 727
acute tubular injury — Ch. 27, p. 791
adaptive immunity — Ch. 21, p. 601
Addison disease — Ch. 23, p. 665
additional precautions — Ch. 4, p. 97
adenoma — Ch. 25, p. 727
adhesions — Ch. 25, p. 727
adjuvant analgesic — Ch. 5, p. 125
adjuvant therapy — Ch. 9, p. 234
adrenal cortex — Ch. 23, p. 665
adrenal crisis — Ch. 23, p. 665
Adrenal Disorders — s. 23.4, p. 665
adrenal insufficiency — Ch. 23, p. 665
adrenal medulla — Ch. 23, p. 665
advance care planning — Ch. 32, p. 943
advance care planning (ACP) — Ch. 10, p. 264
Advance Care Planning and Goals of Care — s. 10.2, p. 264
adverse event following immunization (AEFI) — Ch. 21, p. 601
afterload — Ch. 6, p. 152
age-adjusted D-dimer cut-off — Ch. 15, p. 409
age-related macular degeneration (AMD) — Ch. 36, p. 1075
ageism — Ch. 8, p. 206
agent — Ch. 1, p. 2
Aging, Frailty and Acute Care — s. 8.1, p. 206
agranulocytosis — Ch. 23, p. 665
air leak — Ch. 15, p. 409
air trapping — Ch. 14, p. 380
airborne infection isolation room (AIIR) — Ch. 4, p. 97
airborne precautions — Ch. 4, p. 97
Airway Clearance — s. 12.5, p. 318
airway hyperresponsiveness — Ch. 14, p. 380
airway resistance — Ch. 12, p. 318
alarm fatigue — Ch. 16, p. 439
alarm features — Ch. 24, p. 696
albumin — Ch. 3, p. 67
albuminuria — Ch. 27, p. 791
Alcohol Withdrawal — s. 11.3, p. 290
alcohol withdrawal — Ch. 11, p. 290
alcohol-associated hepatitis — Ch. 26, p. 759
alcohol-related liver disease (ALD) — Ch. 26, p. 759
Alcohol-Related Liver Disease, Acute Liver Failure and Transplant — s. 26.4, p. 759
alcoholic hallucinosis — Ch. 11, p. 290
aldosterone — Ch. 3, p. 67
alkalemia — Ch. 3, p. 67
alkalosis — Ch. 3, p. 67
allergy — Ch. 21, p. 601
allergy (drug) — Ch. 4, p. 97
allodynia — Ch. 5, p. 125
alpha-1 antitrypsin deficiency — Ch. 14, p. 380
alpha-blocker — Ch. 28, p. 822
alternate level of care (ALC) — Ch. 1, p. 2
alveolar–capillary membrane — Ch. 12, p. 318
alveoli — Ch. 12, p. 318
ambulatory blood pressure monitoring (ABPM) — Ch. 19, p. 538
ambulatory surgery — Ch. 7, p. 179
American Sign Language (ASL) — Ch. 36, p. 1075
Amputation — s. 33.6, p. 976
amputation — Ch. 33, p. 976
amyotrophic lateral sclerosis (ALS) — Ch. 32, p. 943
Amyotrophic Lateral Sclerosis and Living With Progressive Neurologic Disease — s. 32.6, p. 943
anaphylaxis — Ch. 6, p. 152
anastomosis — Ch. 25, p. 727
anastomotic leak — Ch. 24, p. 696
androgen deprivation therapy (ADT) — Ch. 28, p. 822
anemia — Ch. 20, p. 569
anemia of inflammation — Ch. 20, p. 569
Anemias — s. 20.2, p. 569
Anesthesia and Sedation — s. 7.4, p. 179
anesthesia assistant — Ch. 7, p. 179
anginal equivalent — Ch. 17, p. 476
angioedema — Ch. 18, p. 504
angiotensin receptor–neprilysin inhibitor (ARNI) — Ch. 18, p. 504
anion gap — Ch. 3, p. 67
ankle-brachial index (ABI) — Ch. 19, p. 538
anogenital warts — Ch. 29, p. 852
anti-Black racism — Ch. 2, p. 35
anti-CCP antibodies — Ch. 34, p. 1008
anti-racism — Ch. 2, p. 35
anti-VEGF therapy — Ch. 36, p. 1075
antibiotic-resistant organism (ARO) — Ch. 4, p. 97
Antibiotic-Resistant Organisms and C. difficile — s. 4.4, p. 97
antibody — Ch. 21, p. 601
anticholinergic burden — Ch. 8, p. 206
anticipatory grief — Ch. 10, p. 264

anticipatory medications — Ch. 10, p. 264
anticoagulant — Ch. 19, p. 538
Anticoagulation — s. 19.7, p. 538
antidiuretic hormone (ADH) — Ch. 3, p. 67
antifibrotic — Ch. 14, p. 380
antigen — Ch. 21, p. 601
antimicrobial stewardship — Ch. 4, p. 97
Antimicrobial Stewardship and the Nurse — s. 4.5, p. 97
antiplatelet therapy — Ch. 31, p. 913
antiretroviral therapy (ART) — Ch. 21, p. 601
antiseizure medication — Ch. 30, p. 883
antiviral — Ch. 13, p. 349
aortic dissection — Ch. 19, p. 538
aortic stenosis — Ch. 18, p. 504
aphasia — Ch. 30, p. 883
aplastic anemia — Ch. 20, p. 569
apnea — Ch. 10, p. 264
apolipoprotein B (ApoB) — Ch. 17, p. 476
apoptosis — Ch. 9, p. 234
appendicitis — Ch. 25, p. 727
appendicolith — Ch. 25, p. 727
aqueous humour — Ch. 36, p. 1075
areflexia — Ch. 32, p. 943
arginine vasopressin deficiency (AVP-D) — Ch. 23, p. 665
arginine vasopressin resistance (AVP-R) — Ch. 23, p. 665
arterial blood gas (ABG) — Ch. 3, p. 67
arteriovenous fistula (AV fistula) — Ch. 27, p. 791
arteriovenous graft (AV graft) — Ch. 27, p. 791
arthritis — Ch. 34, p. 1008
Arthritis and Connective Tissue Disorders — Ch. 34, p. 1008
articular cartilage — Ch. 34, p. 1008
artifact — Ch. 16, p. 439
Artificial Airways and Tracheostomy Care — s. 12.6, p. 318
artificial nutrition and hydration — Ch. 10, p. 264
ASA Physical Status classification — Ch. 7, p. 179
ascending paralysis — Ch. 32, p. 943
ascites — Ch. 26, p. 759
aspiration — Ch. 13, p. 349
aspiration pneumonia — Ch. 13, p. 349
aspiration pneumonitis — Ch. 13, p. 349
asterixis — Ch. 26, p. 759
Asthma — s. 14.2, p. 380
asthma — Ch. 14, p. 380
asthma control — Ch. 14, p. 380
asthma exacerbation — Ch. 14, p. 380
asymptomatic bacteriuria — Ch. 29, p. 852
asymptomatic bacteriuria (ASB) — Ch. 28, p. 822
asystole — Ch. 16, p. 439
atelectasis — Ch. 7, p. 179
atherosclerosis — Ch. 17, p. 476
Atherosclerosis and Cardiovascular Risk — s. 17.1, p. 476
atrial fibrillation (AF) — Ch. 16, p. 439
Atrial Fibrillation and Flutter — s. 16.6, p. 439
atrial flutter — Ch. 16, p. 439
atrioventricular (AV) node — Ch. 16, p. 439
atypical bacteria — Ch. 13, p. 349
audiogram — Ch. 36, p. 1075
AUDIT-C — Ch. 11, p. 290
authorizing mechanism — Ch. 1, p. 2
autoimmune disease — Ch. 34, p. 1008
autoimmunity — Ch. 21, p. 601
Autoimmunity and Adult Immunization — s. 21.6, p. 601
automated external defibrillator (AED) — Ch. 16, p. 439
automated office blood pressure (AOBP) — Ch. 19, p. 538
autonomic dysfunction — Ch. 32, p. 943
autonomic dysreflexia — Ch. 32, p. 943
autonomic neuropathy — Ch. 22, p. 635
autoregulation — Ch. 30, p. 883
axillary lymph node dissection — Ch. 29, p. 852
axis — Ch. 23, p. 665
B symptoms — Ch. 20, p. 569
back slab — Ch. 33, p. 976
bacterial meningitis — Ch. 30, p. 883
balanced solution — Ch. 3, p. 67
bariatric surgery — Ch. 24, p. 696
Barrett esophagus — Ch. 24, p. 696
basal cell carcinoma — Ch. 35, p. 1040
basal insulin — Ch. 22, p. 635
basal-bolus insulin — Ch. 22, p. 635
Beck's triad — Ch. 18, p. 504
Beers Criteria — Ch. 8, p. 206
benign paroxysmal positional vertigo (BPPV) — Ch. 36, p. 1075
benign prostatic hyperplasia (BPH) — Ch. 28, p. 822
Benign Prostatic Hyperplasia and Prostate Surgery — s. 28.5, p. 822
bereavement — Ch. 10, p. 264
best possible medication history — Ch. 1, p. 2
bilateral salpingo-oophorectomy — Ch. 29, p. 852
bilevel positive airway pressure — Ch. 15, p. 409
biliary colic — Ch. 26, p. 759
bilirubin — Ch. 26, p. 759
biofilm — Ch. 35, p. 1040
biologic — Ch. 14, p. 380
biologic therapy — Ch. 25, p. 727
bioprosthetic valve — Ch. 18, p. 504
biopsy — Ch. 29, p. 852
biosimilar — Ch. 22, p. 635
biphasic reaction — Ch. 6, p. 152
bitemporal visual field loss — Ch. 23, p. 665
bladder diary — Ch. 28, p. 822
bladder scanner — Ch. 28, p. 822
bladder training — Ch. 28, p. 822
Bleeding and Clotting Disorders — s. 20.4, p. 569
Blood and Its Tests — s. 20.1, p. 569
blood component — Ch. 20, p. 569
Blood Components and Transfusion — s. 20.6, p. 569
blood culture — Ch. 13, p. 349
blood–brain barrier — Ch. 30, p. 883
Body Fluids and How They Are Regulated — s. 3.1, p. 67
bolus — Ch. 24, p. 696
bolus (prandial) insulin — Ch. 22, p. 635
bone mineral density (BMD) — Ch. 33, p. 976
Bowel Function, Constipation and Diarrhea — s. 25.1, p. 727
bowel obstruction — Ch. 25, p. 727
Bowel Obstruction and Ileus — s. 25.4, p. 727
bowel regimen — Ch. 5, p. 125
brachytherapy — Ch. 9, p. 234
bradykinesia — Ch. 32, p. 943
brainstem — Ch. 30, p. 883

non-invasive ventilation — Ch. 15, p. 409
non-rebreather mask — Ch. 12, p. 318
non-small cell lung cancer (NSCLC) — Ch. 13, p. 349
noncardiogenic pulmonary edema — Ch. 15, p. 409
noninvasive ventilation (NIV) — Ch. 32, p. 943
nonsteroidal anti-inflammatory drug (NSAID) — Ch. 5, p. 125
nonunion — Ch. 33, p. 976
normal sinus rhythm — Ch. 16, p. 439
NSTEMI (non-ST-elevation myocardial infarction) — Ch. 17, p. 476
nucleic acid amplification test — Ch. 29, p. 852
nucleic acid amplification test (NAAT) — Ch. 13, p. 349
numeric rating scale (NRS) — Ch. 5, p. 125
Nurse Specialized in Wound, Ostomy and Continence (NSWOC) — Ch. 25, p. 727
nurse-driven catheter removal protocol — Ch. 28, p. 822
Nursing Care of the Patient in Shock — s. 6.6, p. 152
NYHA functional class — Ch. 18, p. 504
obesity — Ch. 24, p. 696
Obesity and Bariatric Surgery — s. 24.6, p. 696
Obstructive and Restrictive Lung Disease — Ch. 14, p. 380
Obstructive and Restrictive Patterns — s. 14.1, p. 380
obstructive lung disease — Ch. 14, p. 380
obstructive shock — Ch. 6, p. 152
obstructive sleep apnea (OSA) — Ch. 7, p. 179
obturator — Ch. 12, p. 318
OCAP® — Ch. 2, p. 35
occult hypoxemia — Ch. 2, p. 35
offloading — Ch. 35, p. 1040
Older Adults in Acute Care — Ch. 8, p. 206
oliguria — Ch. 27, p. 791
Oncologic Emergencies — s. 9.4, p. 234
oncologic emergency — Ch. 9, p. 234
Ontario Health Team — Ch. 1, p. 2
open fracture — Ch. 33, p. 976
open-angle glaucoma — Ch. 36, p. 1075
opioid — Ch. 5, p. 125
opioid agonist treatment (OAT) — Ch. 5, p. 125
opioid toxicity — Ch. 11, p. 290
Opioid Toxicity and Withdrawal — s. 11.4, p. 290
opioid use disorder (OUD) — Ch. 5, p. 125
opioid withdrawal — Ch. 11, p. 290
opioid-induced respiratory depression (OIRD) — Ch. 5, p. 125
opioid-naive — Ch. 5, p. 125
Opioids: Safe Use in Hospital — s. 5.4, p. 125
opportunistic infection — Ch. 21, p. 601
optic nerve — Ch. 36, p. 1075
organ inventory — Ch. 29, p. 852
orolingual angioedema — Ch. 31, p. 913
oropharyngeal airway — Ch. 12, p. 318
orthopnea — Ch. 18, p. 504
orthostatic hypotension — Ch. 3, p. 67
osmolality — Ch. 3, p. 67
osmolarity — Ch. 3, p. 67
osmosis — Ch. 3, p. 67
osmotherapy — Ch. 30, p. 883
osmotic demyelination syndrome (ODS) — Ch. 3, p. 67
Osteoarthritis — s. 34.2, p. 1008
osteoarthritis (OA) — Ch. 34, p. 1008
osteomyelitis — Ch. 33, p. 976
osteoporosis — Ch. 33, p. 976
Osteoporosis and Bone Health — s. 33.3, p. 976
ostomy — Ch. 25, p. 727
Ostomy Care and Teaching — s. 25.6, p. 727
otitis externa — Ch. 36, p. 1075
otitis media — Ch. 36, p. 1075
ototoxicity — Ch. 36, p. 1075
Ottawa Model for Smoking Cessation — Ch. 14, p. 380
outbreak — Ch. 4, p. 97
outer ear — Ch. 36, p. 1075
outpatient parenteral antibiotic therapy (OPAT) — Ch. 18, p. 504
overdiagnosis — Ch. 9, p. 234
overflow diarrhea — Ch. 25, p. 727
overflow incontinence — Ch. 28, p. 822
oxygen target range — Ch. 12, p. 318
Oxygen Therapy — s. 12.4, p. 318
oxygen–hemoglobin dissociation curve — Ch. 12, p. 318
P wave — Ch. 16, p. 439
P/F ratio — Ch. 15, p. 409
P2Y12 inhibitor — Ch. 17, p. 476
$PaCO_2$ — Ch. 3, p. 67
Pain — Ch. 5, p. 125
pain — Ch. 5, p. 125
Pain Assessment — s. 5.2, p. 125
Pain Assessment in Advanced Dementia (PAINAD) scale — Ch. 5, p. 125
pain sensitization — Ch. 34, p. 1008
Palliative and End-of-Life Care — Ch. 10, p. 264
palliative approach — Ch. 10, p. 264
palliative care — Ch. 10, p. 264
palliative sedation — Ch. 10, p. 264
palmar erythema — Ch. 26, p. 759
pancreatic enzyme replacement therapy (PERT) — Ch. 26, p. 759
papillary muscle rupture — Ch. 17, p. 476
paracentesis — Ch. 26, p. 759
paralytic ileus — Ch. 25, p. 727
paraneoplastic syndrome — Ch. 13, p. 349
paraplegia — Ch. 32, p. 943
parastomal hernia — Ch. 25, p. 727
parathyroid hormone (PTH) — Ch. 23, p. 665
parathyroid hormone–related peptide (PTHrP) — Ch. 9, p. 234
parathyroidectomy — Ch. 23, p. 665
parenteral nutrition — Ch. 24, p. 696
Parkinson Disease — s. 32.4, p. 943
Parkinson disease (PD) — Ch. 32, p. 943
paroxysmal nocturnal dyspnea (PND) — Ch. 18, p. 504
partial agonist — Ch. 5, p. 125
partial-thickness burn — Ch. 35, p. 1040
partner notification — Ch. 29, p. 852
Partnering with Patients Across Transitions — s. 1.7, p. 2
pathologic fracture — Ch. 33, p. 976
patient safety incident — Ch. 1, p. 2
patient- and family-centred care — Ch. 1, p. 2
patient-controlled analgesia (PCA) — Ch. 5, p. 125
Patients Living With Chronic Pain or Opioid Use Disorder — s. 5.5, p. 125
PAWSS — Ch. 11, p. 290

PCA by proxy — Ch. 5, p. 125
PDE5 inhibitor — Ch. 29, p. 852
PE response team (PERT) — Ch. 15, p. 409
peak expiratory flow (PEF) — Ch. 14, p. 380
pelvic floor muscle training (PFMT) — Ch. 28, p. 822
pelvic inflammatory disease — Ch. 29, p. 852
pelvic organ prolapse — Ch. 29, p. 852
penumbra — Ch. 31, p. 913
peptic ulcer disease (PUD) — Ch. 24, p. 696
perception — Ch. 5, p. 125

BUILT FROM THE GROUND UP FOR CANADIAN BSCN & PRACTICAL NURSING CURRICULA

Medical-Surgical Nursing: A Canadian Open Text

Medical-Surgical Nursing: A Canadian Open Text is a comprehensive, 36-chapter open textbook written specifically for Canadian undergraduate and practical nursing students. Every chapter is grounded in Canadian epidemiology, SI laboratory intervals (mmol/L, µmol/L, g/L), Health Canada Drug Product Database nomenclature, provincial and territorial regulatory standards, and national clinical practice guidelines.

Nine-Unit Clinical Structure (36 Chapters • 245 Clinical Figures)

Unit	Chapters	Clinical Scope
Unit I	Chapters 1–6	Canadian Health Systems, Indigenous Cultural Safety, Fluids/Electrolytes, Sepsis, Pain, Shock
Unit II	Chapters 7–11	Perioperative Care, Older Adults in Acute Care, Cancer Care, Palliative Care & MAID, Substance Use
Unit III	Chapters 12–15	Respiratory Assessment, Oxygen Therapy, Pneumonia, Lung Cancer, COPD, Asthma, ARDS & PE
Unit IV	Chapters 16–19	Cardiac Assessment, ECG Dysrhythmias, ACS, Heart Failure, Valvular Disease, Hypertension & Vascular
Unit V	Chapters 20–23	Hematology, Transfusion Therapy, Immunity, Allergy, HIV, Diabetes Mellitus & Endocrine Care
Unit VI	Chapters 24–26	Upper & Lower Gastrointestinal Disorders, Enteral/Parenteral Nutrition, Ostomies, Liver, Biliary & Pancreas
Unit VII	Chapters 27–29	Acute Kidney Injury, Chronic Kidney Disease, Dialysis, Urinary Tract, Prostate & Reproductive Care
Unit VIII	Chapters 30–32	Neurologic Assessment, Increased ICP, Ischemic & Hemorrhagic Stroke, TBI, SCI & Chronic Neurologic Care
Unit IX	Chapters 33–36	Musculoskeletal Trauma, Orthopedic Surgery, Arthritis, Connective Tissue, Wounds, Burns, Eye & Ear Care

Pedagogical Features in Every Chapter

Feature	Educational Purpose
Unfolding Practice Story	Follows 36 unique Canadian nurses (18 RNs, 18 RPNs/LPNs) and adult patients from presentation to discharge.
Canadian Context & OCAP®	Integrates TRC Calls to Action 18–24, Joyce's Principle, NIHB coverage, and rural/northern transport.
RN / RPN / LPN Scope Boxes	Applies CNO's Scope of Practice framework (authority, competence, and context) across provincial regulations.
1,310 Licensure Review Items	30 to 40 NCLEX-RN, REx-PN, and CPNRE questions per chapter (with unfolding case clusters and full rationales).

About the Author: Andrew Lee, BEd, BN, MN, RN, CCN(C) is a Professor of Nursing at Loyalist College in Belleville, Ontario. Holding degrees in Education and Nursing and Canadian Nurses Association certification in Cardiovascular Nursing (CCN(C)), his clinical and academic work focuses on adult acute medical-surgical nursing, clinical judgment, and open nursing education.
